Emulation for the Motorola MPC82XX
Agilent Technologies E5900B Option 100 Emulation Probe—At a Glance

This manual describes how to set up:

- an emulation probe
- an emulation module
- an emulation migration

The emulation probe provides a low-cost way to debug embedded software for Motorola MPC82XX family microprocessors. The emulation probe lets you use the target processor's built-in debugging features, including: run control, register access, and memory access. A high-level source debugger can use the emulation probe to debug code running on the target system.

The emulation probe can be controlled by a debugger on a host computer or by the Emulation Control Interface on an Agilent 16700-series logic analysis system. The emulation probe communicates with a host computer or logic analysis system via LAN.

E5900B Emulation Probe

![Diagram of E5900B Emulation Probe setup](image)
E5901B Emulation Module Kit

The Agilent E5901B emulation module kit includes the E5900B emulation probe, the E5901B emulation module, and other items listed on page 18. The Agilent E5901B emulation module plugs into your Agilent 16700-series logic analysis system frame. It provides power, cross triggering, and limited communication for the E5900B emulation probe through the module/probe interconnect cable. The logic analysis system communicates with the target system through the LAN connection to the E5900B emulation probe.

E5902B Emulation Migration Kit

The emulation migration includes the parts needed to use an emulation probe for a new processor family.

Overview
Chapter 1: Overview

This chapter describes:

• Setup flowchart
• Equipment used with the emulation probe
• Equipment used with the emulation module
• Equipment used with the emulation migration
• Connection sequences for the emulation probe
• Additional information sources
Chapter 1: Overview
Setup Flowchart

Setup Flowchart

Emulation module
- Install emulation module (if necessary)
- Connect emulation probe to emulation module
- Connect emulation probe to LAN

Emulation probe
- Connect power supply
- Connect to LAN

Emulation migration
- Install new target board adapter and front panel in emulation probe

Install software on logic analysis system

Update emulation probe firmware (if necessary)

Connect emulation probe to target system or analysis probe

Installation done. Begin making measurements.

Minimum equipment required

The following equipment is required to use the emulation probe:

- A method for connecting the emulation probe to the target system. The target system must have an appropriate JTAG (Joint Test Action Group) debug port connector. The target system must meet the criteria described in Chapter 2, “Designing a Target System for an Emulation Probe,” beginning on page 25.
- A host computer, such as a PC or workstation. You can also connect the emulation probe to an Agilent 16700-series logic analysis system.
- A LAN (local area network) if you want to connect the emulation probe to a host computer.
- A user interface on the host computer, such as a high-level source debugger or the logic analysis system’s Emulation Control Interface.

Agilent E5901B Emulation Module Kit

Equipment supplied

The Agilent E5901B emulation module facilitates communication between the Agilent 16700-series logic analysis system and the Agilent E5900B emulation probe. If you ordered an emulation module as part of your Agilent 16700-series logic analysis system, it is already installed in the frame.

The equipment supplied with your emulation module includes:

• All of the parts listed for the Agilent E5900B emulation probe on page 16 (except the serial cable and RJ12-to-DB9 adapter), and:

</tbody>
</table>

Minimum equipment required

The following equipment is required to use the emulation migration:

- An Agilent E5900B emulation probe.
- A method for connecting the emulation probe to the target system. The target system must have an appropriate JTAG debug port connector. The target system must meet the criteria described in Chapter 2, “Designing a Target System for an Emulation Probe,” beginning on page 25.
- A host computer such as a PC, a workstation, or an Agilent 16700-series logic analysis system.
- A user interface, such as a high-level source debugger or the logic analysis system's Emulation Control Interface.
Chapter 1: Overview

To connect the emulation probe to a power source

The emulation probe is shipped from the factory with a power supply and cord appropriate for your country. (The power supply you received may look different from the one illustrated below.) If the cord you received is not appropriate for your electrical power outlet type, contact your Agilent Technologies sales and service office.

WARNING:  
Use only the supplied Agilent power supply and cord. Failure to use the proper power supply could result in electric shock.

CAUTION:  
Use only the supplied Agilent power supply and cord. Failure to use the proper power supply could result in equipment damage.

1 Install the ferrite on the 12V power cord, near the end which plugs into the emulation probe.

2 Connect the power cord to the power supply and to a socket outlet.

3 Connect the 12V power cord to the back of the emulation probe.
Chapter 1: Overview

To connect the emulation probe to a power source

4 Turn on the emulation probe power switch.

---

Connection Sequence

Disconnect power from the target system, emulation probe, and logic analyzer before you make or break connections.

1 Connect the emulation probe to a LAN (page 37).
2 Connect the emulation probe to your target system (page 59).
3 Configure the emulation probe (page 63).

---

To power on the system

With all components connected, power on your system as follows:

1 Logic analyzer, if you are using one.
2 Emulation probe.
3 Your target system.

---

To power off the system

Power off your system as follows:

1 Your target system.
2 Emulation probe.
3 Logic analyzer, if you are using one.
Additional Information Sources

Additional or updated information can be found in the following places:

Newer editions of this manual may be available. Contact your local Agilent Technologies representative.

If you ordered an inverse assembler, the manual supplied with your inverse assembler will provide additional information.

If you have an analysis probe, the instructions for connecting the probe to your target microprocessor are in the analysis probe documentation. The documentation supplied with the analysis probe provides information about using the analysis probe and emulation probe together.

Application notes may be available from your local Agilent representative or on the World Wide Web at:

http://www.agilent.com/find/emulator

If you have an Agilent 16700-series logic analysis system, the online help for the Emulation Control Interface has additional information on using the emulation probe.

The measurement examples include valuable tips for making emulation and analysis measurements. You can find the measurement examples under the system help in your Agilent 16700-series logic analysis system.

Designing a Target System for an Emulation Probe
This chapter will help you design a target system that will work with the emulation probe.

Target System Requirements

Unsupported modes

Target systems that use any of the following modes of operation are not currently supported:

- Address parity is not generated on external address bus operations. Accesses to devices that check parity will fail.

TDO, TDI, TCK, TMS and TRST signals

TDO, TDI, TCK, TMS and TRST signal traces between the JTAG debug port connector and the processor must be less than 3 inches long. If these signals are connected to other nodes, the other nodes must be daisy chained between the JTAG connector at one end and the PowerPC microprocessor at the other end. These signals are sensitive to crosstalk and must not be routed along active signals such as clock lines on the target board.

The TDI, TCK, TMS and TRST signals must not be actively driven by the target system when the JTAG debug port is being used.

Reset Vector Address

After a system reset, the processor can be directed to boot from one of two locations. This allows the developer flexibility in booting from either ROM or RAM.

You can choose the start location after a reset by using the reset operation configuration command (see page 69) and the reset vector configuration command (see page 69). The location can be fff00100 (the traditional location of ROM) or 00000100 (a RAM reset location). The use of a RAM location allows you to rapidly re-compile, load, and then test your boot-up sequence without having to re-flash ROM.
Chapter 2: Designing a Target System for an Emulation Probe

Reset signals

The HRESET, SRESET and TRST signals from the JTAG connector must be wire ORed with the HRESET, SRESET and TRST signals that connect to the processor on the target system.

MPC82XX Target Processor PC Board

The emulation probe adds capacitance to all target system signals routed to the JTAG debug port connector. This added capacitance may increase the rise time and/or fall time of the reset signals beyond target processor specifications. Decreasing the value of the pull-up resistor on a line will decrease its rise time.

Consult the following sources for more information:

- See the tables on page 29 for recommended pull-up resistor values.
- See the tables on page 168 for emulation probe input and output
capacitance values.

- See the processor manufacturer's data sheet for rise/fall time specifications.

### PowerPC JTAG interface connections and resistors

The target system must have a 16-pin male 2x8 header connector with dimensions as shown below.

![JTAG Header Connector (top view)](image)

**JTAG Header Connector (top view)**

Position 14 of the connector on the target system must not contain a pin. The cable supplied with the emulation probe can only be installed if pin 14 has been removed from the target system header.

Place the connector as close as possible to the processor to ensure signal integrity.

</tbody>
</table>

1. To ensure TAP stability some processors may require TRST to be held low when the emulation probe is not connected to the target. In this case a 2 kΩ pulldown resistor can be used instead of a 10 kΩ pullup resistor.

2. The +POWER signal (also called Vref) is sourced from the target system and is used as a reference signal. It should be the power signal being supplied to the processor (in the range of 2.0 V to 5.0 V). It does not supply power to the emulation probe.

3. This 1 kΩ series resistor provides short circuit current limiting protection only. If the resistor is present, it should be 1 kΩ or less.

4. If the target system does not use QACK, the board must have a 1 kΩ pulldown resistor connected to this pin. This signal allows the emulation probe to force the processor into soft stop mode. If the target system does use this signal, it should provide logic so that QACK goes low in response to a QREQ.
Chapter 2: Designing a Target System for an Emulation Probe
Installing the Optional Emulation Module
Chapter 3: Installing the Optional Emulation Module

This chapter shows you how to install the optional emulation module in your Agilent Technologies 16700-series logic analysis system and how to connect the emulation module to an emulation probe.

If you are not using an Agilent logic analysis system with your emulation probe, or if your emulation module is already installed in your logic analysis system frame, you may skip this chapter.

**CAUTION:**
Electrostatic discharge (ESD) can damage electronic components. Observe standard ESD precautions. Use grounded wrist straps and mats when you handle modules.

You will need to set up a LAN connection for the E5900B emulation probe, even if you are using an E5901B emulation module.
To install the emulation module in an Agilent 16700-series logic analysis system or expansion frame

You will need T-10 and T-15 Torx screw drivers (supplied with the emulation module)

1 Turn off the logic analysis system and REMOVE THE POWER CORD. Remove any other cables (including mouse or video monitor cables).

2 Turn the logic analysis system frame upside-down.

3 Remove the bottom cover.

4 Remove the slot cover.

NOTE: The 16700B-series logic analysis system (which is shown here) has one available slot. If you have a 16700A-series logic analysis system, you may use either of the two slots.
Chapter 3: Installing the Optional Emulation Module

5 Install the emulation module.

6 Connect the cable and re-install the screws.

NOTE: The 16700B-series logic analysis system (which is shown here) has one available connector. If you have a 16700A-series logic analysis system, you may connect the cable to either of the two connectors.

7 Reinstall the bottom cover, then turn the frame right-side-up.

8 Plug in the power cord, reconnect the other cables, and turn on the logic analysis system.

The new emulation module will be shown as an "E5901B Emulation Module" in the system window.
To connect the E5901B emulation module to the E5900B emulation probe

1. Connect one end of the module/probe interconnect cable to the E5901B emulation module in the logic analysis system mainframe.

2. Connect other end of the module/probe interconnect cable to the "Emulation Module" connector on the E5900B emulation probe.

3. Power on the emulation probe.
   The LED next to the switch is lit when the switch is turned on and the probe is being supplied with power.
   Power is supplied by the 16700-series logic analysis system through the module/probe interconnect cable. The external power supply is not necessary for normal operation.

See Also

Chapter 4, “Connecting the Emulation Probe to a LAN,” beginning on page 37. (You need to connect the emulation probe to the LAN, even when you are using an emulation module.)

Chapter 6, “Connecting the Emulation Probe to Your Target System,” beginning on page 59.
Chapter 3: Installing the Optional Emulation Module
Connecting the Emulation Probe to a LAN
To choose a point-to-point or site LAN connection

The emulation probe has an IEEE 802.3 Type 10/100Base-TX LAN connector. The emulation probe is compatible with both 10 Mbps (10BASE-T) and 100 Mbps (100BASE-TX) twisted-pair ethernet LANs. The probe automatically negotiates the data rate for the LAN it is connected to.

Before the Emulation Control Interface can connect to the emulation probe, the probe's LAN parameters (that is, its IP address, gateway address, and subnet mask) must be set up. The IP address and other network parameters are stored in nonvolatile memory within the emulation probe.

See Also

For information on connecting a debugger to the emulation probe, see Chapter 8, “Using the Emulation Probe,” beginning on page 81.
Advantages of a point-to-point connection:

- If you have an E5901B emulation module, all LAN parameters will be set automatically.
- No need for a system administrator to assign IP addresses. (You can use any IP address for the emulation probe, and it will not conflict with other devices on the LAN.)
- The logic analysis system cannot be accessed across the network (required in some high-security environments).
- Can be used when a site LAN is not available.

Disadvantages of a point-to-point connection:

- Neither logic analysis system nor the emulation probe are connected to a site LAN.
- A special "crossover" LAN cable must be used.

If you have an emulation module, use the LAN crossover cable supplied with the emulation module (Agilent part number 5061-7342). If you do not have an emulation module, use a Category 3 (for 10BASE-T) or Category 5 (for 100BASE-TX) crossover cable.
- The emulation probe must be near the logic analysis system. The length of the crossover cable supplied with the emulation module is 1.5m (5 feet).
- Remote file systems cannot be mounted for access to source code files, symbol files, or executable files.
- The emulation probe cannot be controlled by a debugger on a host computer.
Connecting the Emulation Probe to a Site LAN

1 Connect the LAN cable to the connector on the emulation probe.

Be sure to use the appropriate Category 3 or Category 5 cable for your LAN. Do not use the LAN cable supplied with the emulation probe—it is a crossover cable used for point-to-point connections only.

2 Find out the IP address and other LAN parameters to use for the emulation probe. See “To obtain an IP address” on page 41.

3 Decide how you want to configure the LAN parameters:

<table>
<thead>
<tr>
<th>If you have this equipment...</th>
<th>Use this procedure</th>
</tr>
</thead>
<tbody>
<tr>
<td>Emulation probe only</td>
<td>“To configure LAN parameters using a serial connection” on page 42, or “To configure LAN parameters using DHCP” on page 45</td>
</tr>
<tr>
<td>Emulation probe and a logic analysis system without an E5901B emulation module</td>
<td>“To configure LAN parameters using a logic analysis system without an emulation module” on page 47</td>
</tr>
<tr>
<td>Emulation probe and a logic analysis system with an E5901B emulation module</td>
<td>“To configure LAN parameters using a logic analysis system with an emulation module” on page 48</td>
</tr>
</tbody>
</table>

4 Verify that your emulation probe is now active and on the network. See “To verify LAN communications” on page 51.
To obtain an IP address

1 Obtain the following information from your local network administrator or system administrator:

   • An IP address for the emulation probe.
     You can also use a "LAN name" for the emulation probe, but you must configure it using the integer dot notation (such as 127.0.0.1).
   • The gateway address.
     The gateway address is an IP address and is entered in integer dot notation. The default gateway address is 0.0.0.0, which allows connections only on the local network or subnet. If connections are to be made to workstations on other networks or subnets, this address must be set to the address of the gateway machine.
   • The subnet mask.
     A subnet mask blocks out part of an IP address so that the networking software can determine whether the destination host is on a local or remote network. It is usually represented as decimal numbers separated by periods; for example, 255.255.248.0.

2 Find out whether port numbers 6470 and 6471 are already in use on your network and if that use constitutes a conflict.

   The host computer interfaces communicate with the emulation probe through two TCP service ports. The default base port number is 6470. The second port has the next higher number (default 6471).

   In almost all cases, the default numbers (6470, 6471) can be used without change. If necessary the base port number can be changed if the port numbers conflict with some other product on your network.

   To change the port numbers, see page 44. If you have already set the IP address, you can use a telnet connection instead of a serial connection to connect to the emulation probe.
Connecting the Emulation Probe to a Site LAN

To configure LAN parameters using a serial connection

The E5900B emulation probe has a 9600 baud RS-232 serial interface with an RJ12 connector.

The emulation probe is shipped with a serial cable (with RJ-12 connectors on both ends, with 6-wire straight-through connections) and an adapter (female RJ-12 to female 9-pin D subminiature). The adapter plugs into the 9-pin serial port found on most PCs.

Serial connections on a workstation

If you are using a UNIX® workstation as the host computer, you need to use a serial device file. If a serial device file does not already exist on your host, you need to create one. Once it exists, you need to ensure that it has the appropriate permissions so that you can access it. See the system documentation for your workstation for help with setting up a serial device.

Serial connections on a PC

Serial connections are supported on PCs. You must use hardware handshaking if you will use the serial connection for anything other than setting LAN parameters.

If you are using a PC as the host computer, you do not need to set up any special files.
1 Connect the serial cable from the host computer to the emulation probe. Use the DB9-to-RJ12 adapter and the serial cable supplied with the emulation probe.

2 Start a terminal emulator program on the host computer.

   If you are using a PC, the HyperTerminal application in Microsoft® Windows® will work fine.

   If you are using a UNIX workstation, you can use a terminal emulator such as cu or kermit.

3 Configure the terminal emulator program for:
   - Communication rate: 9600 baud
   - Bits: 8
   - Parity: none
   - Stop bits: 1
   - Flow control: none

4 Turn on power to the emulation probe.

   When the emulation probe powers up, it sends a version message to the serial port, followed by a prompt.

5 Press the Return or Enter key a few times.
Chapter 4: Connecting the Emulation Probe to a LAN

Connecting the Emulation Probe to a Site LAN

You should see a prompt such as "p>" or "R>".

For information about the commands you can use, enter ? or help at the prompt.

6 Display the current LAN configuration values by entering the `lan` command:

   R> lan
   lan is enabled
      Link Status is UP
      100BaseTX
   lan -i 15.5.24.116
   lan -g 15.5.23.1
   lan -s 255.255.248.0
   lan -p 6470
   Ethernet Address : 08000909BAC1
   R>

   The Ethernet address, also known as the link level address, is preassigned at the factory, and is printed on a label on the emulation probe.

7 Enter the following command:

   lan -i <internet> [-g <gateway>] [-p <port>] [-s <subnet>]

   The lan command parameters are:

   -i <internet>  The IP address which you obtained from your network administrator.
   -g <gateway>  The gateway address. Setting the gateway address allows access outside your local network or subnet.
   -s <subnet>  This changes the subnet mask.
   -p <port>  This changes the base TCP service port number, normally 6470.

   Do not change the default port numbers (6470, 6471) unless they conflict with some other product on your network. The numbers must be greater than 1024. If you change the base port, enter the new value in the configuration of your debugger (and, for UNIX workstations, in the /etc/services file).

8 Cycle power on the emulation probe.

   The IP address and any other LAN parameters you change are stored in nonvolatile memory and will take effect when the emulation probe is powered.
Chapter 4: Connecting the Emulation Probe to a LAN

Connecting the Emulation Probe to a Site LAN

9 Verify your emulation probe is now active and on the network. See “Verifying LAN Communications” on page 51.

Once you have set a valid IP address, you can use the telnet utility to connect to the emulation probe, and use the lan command to change LAN parameters.

<table>
<thead>
<tr>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>To assign an IP address of 192.6.94.2 to the emulation probe, enter the following command:</td>
</tr>
<tr>
<td>R&gt;lan -i 192.6.94.2</td>
</tr>
<tr>
<td>Cycle power on the emulation probe so that the new address will take effect.</td>
</tr>
</tbody>
</table>

To configure LAN parameters using DHCP

If there is a DHCP server on your network which responds to BOOTP requests and supports “static allocation” of IP addresses, it can be used to set the emulation probe’s LAN parameters.

1 Ask your system administrator to set up an IP address for the emulation probe on the DHCP server.

You will need to supply the link-level address of the emulation probe.

The link-level address (LLA) is printed on a label above the LAN connector on the emulation probe. This address is configured in each emulation probe shipped from the factory and cannot be changed.

2 Connect the LAN cable to the connector on the emulation probe.

3 Cycle power on the emulation probe by powering it off then on again.

4 Wait at least 20 seconds for the emulation probe to recognize the LAN.

5 Verify that your emulation probe is now active and on the network. See “To verify LAN communications” on page 51.
What is DHCP?

DHCP (Dynamic Host Configuration Protocol) allows clients to obtain LAN parameters automatically from a server.

How does the emulation probe use DHCP?

The emulation probe uses “static allocation” (sometimes called “manual allocation”) to obtain a permanent IP address. Every time the emulation probe is turned on, it sends out a BOOTP request packet. If the DHCP server on the network responds to BOOTP requests and has been configured to reply to the emulation probe’s link-level address, it will respond with the IP address and other LAN parameters.

The emulation probe does not support “automatic allocation”, which permanently allocates IP addresses from a pool of addresses.

Nor does the emulation probe support “dynamic allocation” of IP addresses—it does not track lease duration and request a new IP address when the lease is about to expire.

How does DHCP interact with other methods of setting LAN parameters?

Every time the emulation probe is turned ON, it sends out a BOOTP request packet (even if the LAN parameters have already been configured). As long as the DHCP server is configured to reply to BOOTP requests from the emulation probe’s link-level address, it will respond with the IP address and other LAN parameters.
To configure LAN parameters using a logic analysis system without an emulation module

1. Connect the LAN cable to the connector on the emulation probe.

2. In the logic analysis system interface, open the Workspace window by selecting the Workspace icon.

3. Scroll down the left side of the toolbox in the workspace window and find the emulation probe tool. Drag the emulation probe icon from the toolbox to the workspace.

4. From the emulation probe icon, select Init Probe LAN Addresses....

5. Enter the link-level address of the probe you wish to set up.

6. Enter the internet address, gateway IP and subnet mask in the appropriate fields.

7. Select OK.

   If "ERROR - no response from emulation probe" is displayed, check that the emulation probe is properly connected to the LAN. Then try selecting OK again.

   If no error message is displayed, the internet address and other network parameters will be stored in nonvolatile memory and will take effect when power is cycled.

8. Cycle power on the emulation probe by powering it off then on again.
To configure LAN parameters using a logic analysis system with an emulation module

1. Connect the emulation module to the emulation probe. (See page 35.)
2. Connect the LAN cable to the connector on the emulation probe.
3. Cycle power on the emulation probe by powering it off then on again.
4. Wait at least 20 seconds for the emulation probe to recognize the LAN.
5. From the E5901B emulation module icon, select Modify Interconnected Probe LAN Addresses.
6. Select Read Probe Addresses to read the current settings.
7. Enter the internet address, gateway IP and subnet mask in the appropriate fields.
8. Select OK.
9. Cycle power on the emulation probe. The new addresses will take effect after you cycle power.
Chapter 4: Connecting the Emulation Probe to a LAN

Setting up a Point-to-Point Connection

A point-to-point connection creates an isolated network with only two nodes—the logic analysis system and the emulation probe.

There are two ways to set up the connection:

<table>
<thead>
<tr>
<th>If you have this equipment...</th>
<th>Use this procedure</th>
</tr>
</thead>
<tbody>
<tr>
<td>Emulation probe and a logic analysis system <em>with</em> an E5901B emulation module</td>
<td>“To set up a point-to-point connection with an emulation module” on page 49</td>
</tr>
<tr>
<td>Emulation probe and a logic analysis system <em>without</em> an E5901B emulation module</td>
<td>“To set up a point-to-point connection without an emulation module” on page 50</td>
</tr>
</tbody>
</table>

To set up a point-to-point connection with an emulation module

1. Connect the emulation module to the emulation probe (page 35).
2. Connect the crossover LAN cable between the logic analysis system and the emulation probe.
3. In the logic analysis system main window, open the System Administration dialog and check that networking is enabled.
4. Select the emulation module icon then select Start Session....

This will automatically configure the LAN connection and start the Emulation Control Interface. There is no need to set the IP address of the emulation probe.
Chapter 4: Connecting the Emulation Probe to a LAN

Setting up a Point-to-Point Connection

To set up a point-to-point connection without an emulation module

1. Connect the crossover LAN cable between the logic analysis system and the emulation probe.
2. Turn on power to the emulation probe.
3. In the logic analysis system main window, select the System Administration icon.
4. Select Network Setup....
5. Select Standard to turn on networking.
   Leave the network parameters with the default values. The IP address should be 192.0.2.231.
7. In the Network Setup dialog, select OK.
8. In the main system window, select the Workspace icon.
9. Drag the emulation probe icon onto the workspace.
10. From the emulation probe icon, select Init Probe LAN Addresses....
11. Enter the link-level address of the emulation probe.
   The link-level address (LLA) is printed on a label above the LAN connector on the emulation probe.
12. Enter the following IP address: 192.0.2.233
13. Select OK then follow the instructions.

Note about the Setup Assistant: If networking is disabled for the 16700-series logic analysis system, the Setup Assistant will guide you through the process of setting up a point-to-point connection. If networking is enabled, the Setup Assistant assumes you want to connect the emulation probe to a site LAN.
Verifying LAN Communications

Verify your emulation probe is now active and on the network by issuing a ping or telnet command to the IP address.

To verify LAN communications using ping

These instructions assume you are using a PC running Microsoft Windows 95 or Windows 98. The procedure for other operating systems is slightly different.

1. Open an MS-DOS® window or select Start→Run....
2. Enter the ping command followed by the IP address of the emulation probe.

Example

C:\WINDOWS>ping 15.6.253.138
Pinging 15.6.253.138 with 32 bytes of data:
Reply from 15.6.253.138: bytes=32 time=1ms TTL=254
Reply from 15.6.253.138: bytes=32 time=1ms TTL=254
Reply from 15.6.253.138: bytes=32 time=1ms TTL=254
Reply from 15.6.253.138: bytes=32 time<10ms TTL=254

If You Have Problems

If the response is something like "100% packet loss" or "Destination host unreachable", see “Problems with the LAN Interface” on page 150.
Chapter 4: Connecting the Emulation Probe to a LAN

Verifying LAN Communications

To verify LAN communications using telnet

1. Verify your emulation probe is now active and on the network by issuing a telnet to the IP address. This connection will give you access to the emulation probe’s built-in terminal interface.

2. To view the LAN parameters, enter the lan command at the terminal interface prompt.

3. To exit from this telnet session, type Ctrl+D at the prompt.

The best way to change the emulation probe’s IP address, once it has already been set, is to telnet to the emulation probe and use the terminal interface lan command to make the change. Remember, after making your changes, you must cycle power before the changes take effect. Doing this will break the connection and end the telnet session.

To use telnet on a 16700-series logic analysis system, select the System Administration icon, select the Networking tab, then select telnet....

If You Have Problems See “Problems with the LAN Interface” on page 150.

Example

```
$ telnet 192.35.12.6
R>lan
lan is enabled
lan -i 192.35.12.6
lan -g 0.0.0.0
lan -s 255.255.254.0
lan -p 6470
Ethernet Address : 08000F090B30
```
Installing Software on a 16700-Series Logic Analysis System
This chapter explains how to install the software you will need for your analysis probe.

**Installing and loading**

**Installing** the software will copy the files to the hard disk of your logic analysis system. Later, you will need to **load** some of the files into the appropriate hardware module.
What needs to be installed

16700-series logic analysis systems

If you ordered this emulation probe on the same order with your logic analysis system, the software was installed at the factory.

The following files are installed when you install a processor support package from the CD-ROM:

- Logic analysis system configuration files
- Inverse assembler (automatically loaded with the configuration files)
- Personality files for the Setup Assistant
- Emulation module firmware
- Emulation Control Interface

The B4620B Source Correlation Tool Set is installed with the logic analysis system's operating system.
Chapter 5: Installing Software on a 16700-Series Logic Analysis System

To install the software from CD-ROM

Installing a processor support package from a CD-ROM will take just a few minutes. If the processor support package requires an update to the Agilent Technologies 16700 operating system, installation may take approximately 15 minutes.

**NOTE:**
The 16700B-series logic analysis systems have internal CD-ROM drives. The 16700A-series logic analysis systems have external CD-ROM drives.

If your system uses an external CD-ROM drive and it is not connected, see the connection instructions printed on the CD-ROM package.

1. If your system uses an external CD-ROM drive, turn on the CD-ROM drive first and then turn on the logic analysis system. Otherwise, simply turn on the logic analysis system.

   If the CD-ROM and analysis system are already turned on, be sure to save any acquired data. The installation process may reboot the logic analysis system.

2. Insert the CD-ROM in the drive.

3. Select the **System Administration** icon.

4. Select the **Software Install** tab.

5. Select **Install**.

   Change the media type to "**CD-ROM**" if necessary.

6. Select **Apply**.

7. From the list of types of packages, double-click "**PROC-SUPPORT**."

   A list of the processor support packages on the CD-ROM will be displayed.

**NOTE:**
For touch screen systems, double select the "**PROC-SUPPORT**" line by quickly touching it twice.

8. Select the MPC82XX package.

   If you are unsure whether this is the correct package, select **Details** for information about the contents of the package.
9 Select **Install**.
   The Continue dialog box will appear.

10 Select **Continue**.
   The Software Install dialog will display "Progress: completed successfully" when the installation is complete.

11 If required, the system will automatically reboot. Otherwise, close the software installation windows.

   The configuration files are stored in a subdirectory of /logic/configs/hp. The inverse assemblers are stored in /logic/ia.

**See Also**

   See the instructions printed on the CD-ROM package for a summary of the installation instructions.

   See the online help for more information on installing, licensing, and removing software.

---

**To list software packages which are installed (16700)**

   In the System Administration Tools window, under the **Software Install** tab, select **List...**
Connecting the Emulation Probe to Your Target System
Chapter 6: Connecting the Emulation Probe to Your Target System

This chapter shows you how to connect the emulation probe to the target system and how to configure the emulation probe and target.

Here is a summary of the steps for connecting and configuring the emulation probe:

1. Make sure the target system is designed to work properly with the emulation probe. (See page 25.)
2. Install the emulation module in your logic analysis system, if necessary. (See page 31.)
3. Connect the emulation probe to a LAN. (See page 37.)
4. Connect the emulation probe to your target system using the ribbon cable. (See page 61.)
5. Update the firmware of the emulation probe, if necessary. (See page 111.)
6. Configure the emulation probe. (See page 63.)
7. Connect a debugger to the emulation probe, if applicable. (See page 83.)
Chapter 6: Connecting the Emulation Probe to Your Target System

To connect the emulation probe to the target system

The emulation probe can be connected to a target system through a 16-pin JTAG port connector (a 16-pin male 2x8 header connector on the target system).

The emulation probe should be connected to the target system using the ribbon cable provided.

1. Turn off power to the target system.
2. Turn off power to the emulation probe.
3. Plug the un-keyed end (pin 14 is open) of the ribbon cable into the emulation probe.
Chapter 6: Connecting the Emulation Probe to Your Target System

4 Plug the keyed end of the cable (pin 14 is blocked) into the JTAG debug port on the target system.

5 Turn on power to the emulation probe.

6 Turn on power to the target system.

After you have connected the emulation probe to your target system, you may need to update the firmware in the emulation probe.

See Also

For information on designing a debug port on your target board, see page 26.
For a list of the parts supplied with the emulation probe, see page 16.
Configuring the Emulation Probe
Chapter 7: Configuring the Emulation Probe

The emulation probe has several user-configured options. These options may be customized for specific target systems.

Other ways to configure the emulation probe are by using:
- The emulation probe's built-in terminal interface
- Your debugger, if it provides an “emulator configuration” window which can be used with this emulation probe

What can be configured

The following options can be configured using built-in commands:
- Processor type
- JTAG clock speed
- Reset operation
- Reset vector address
- Memory model
- Address translation
- Checkstop status
- Break in behavior
- Trigger out behavior
- Restriction to real-time runs
- Memory read delay
- Memory write delay
- Voltage reference
- Voltage threshold
- Memory mapped registers (MPC8260/64/65/66 only)
- To configure 32-bit mode (MPC8240 only)

The chapter concludes with a section on disabling processor caches.
Configuration items

Configuration items can be changed using the various `cf <item>` commands listed in this chapter. Configuration information is stored in non-volatile memory, so the changes you make to the emulation probe configuration will remain in effect even if you cycle power to the emulation probe.

To restore the emulation probe configuration to factory default settings, issue the `cf default` command.

To configure the processor type

**Processor type configuration**

</tbody>
</table>
Chapter 7: Configuring the Emulation Probe

Configuration items

To configure the JTAG clock speed (communication speed)

The emulation probe needs to be configured to communicate at a rate which is compatible with your target processor. The JTAG clock speed is independent of processor clock speed.

With some target systems that have additional loads on the JTAG lines or with target systems that do not quite meet the requirements (described in Chapter 2, “Designing a Target System for an Emulation Probe,” beginning on page 25), setting speed to a slower setting may enable the emulation probe to work.

The speed value is a number followed by either K, which indicates the value is in kHz, or M, which indicates the value is in MHz. The clock can be set to speeds in the range 512 kHz to 40 MHz. Not all values in this range are valid; if an invalid speed is entered, the next slower valid speed will be used.

Entering `cf speed` without a value will display the current JTAG clock speed.

**JTAG clock speed configuration**

</tbody>
</table>

See Also

“Configuring the Emulation Probe for Maximum Performance” on page 67
Configuring the Emulation Probe for Maximum Performance

The performance of the emulation probe depends on the speed at which it communicates with the target system. Better performance is obtained with faster communication speeds.

Setting TCK speed

On JTAG debug ports the communication speed is controlled by the clock signal TCK. This signal is generated by the emulation probe. You can set the speed of TCK using the Emulation Control Interface in a 16700-series logic analysis system or by using the `cf speed` command through a telnet or debugger connection to the emulation probe.

To change TCK speed, send a `cf speed=x` command to the probe. To restore factory defaults, send a `cf default` command. For more information about `cf speed`, send a `help cf speed` command to the probe. Also note that some debuggers allow the speed to be set from within their GUI or from a command file.

When to decrease TCK speed

Emulation probes are configured at the factory with a default TCK speed. In most cases, this is equal to the maximum allowable speed as specified by the manufacturer (see the table). This speed is suitable for most applications. However, this speed is only valid if 1) the processor is running at its full rated speed, 2) trace lengths from the processor to the JTAG connector are short (two inches or less), and 3) there are no stubs on the JTAG signals. If the emulation probe cannot communicate reliably with the target system using the factory default speed, TCK speed must be reduced.

When to increase TCK speed

Some target systems will allow TCK speeds greater than the default. The real maximum speed for a given target system can be determined empirically by increasing the speed and observing if the communication to the target is reliable. However, please note that speeds greater than the default are not officially supported by Agilent or the chip manufacturer.

</thead>
<tbody>
<tr>
<td>run</td>
<td>Issuing the rst command will hard reset the processor, reset the JTAG interface, and allow the processor to run. (Default)</td>
<td>cf reset=run</td>
</tr>
<tr>
<td>stop</td>
<td>Issuing the rst command will hard reset the processor, reset the JTAG interface, and cause the processor to stop at the reset exception vector 0xfff00100 or 0x00000100. The address used is determined by the config item 'vector'.</td>
<td>cf reset=stop</td>
</tr>
</tbody>
</table>

To configure reset vector address

The reset vector address configuration item specifies which reset vector the target hardware is using. This value does not set the reset vector. This is done by the hardware.

**Vector address configuration**

<table>
<thead>
<tr>
<th>Value</th>
<th>Emulation module configured for</th>
<th>Built-in command</th>
</tr>
</thead>
<tbody>
<tr>
<td>fff00100</td>
<td>Default</td>
<td>cf vector=fff00100</td>
</tr>
<tr>
<td>00000100</td>
<td></td>
<td>cf vector=00000100</td>
</tr>
</tbody>
</table>
Chapter 7: Configuring the Emulation Probe

Configuring the Emulation Probe for Maximum Performance

To configure the memory model

You can use a cache coherency or a physical memory model for memory reads and writes. If both instruction and data caches are off (bits HID0[ICE] and HID0[DCE] are zero), this configuration setting has no effect and memory reads return the contents of physical memory.

Memory model configuration

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
<th>Built-in command</th>
</tr>
</thead>
<tbody>
<tr>
<td>cache</td>
<td>Use the cache coherency model. This model assumes instructions and data are separate, and will not occur within the same cache block (way). (Default)</td>
<td>cf memmodel=cache</td>
</tr>
<tr>
<td>physical</td>
<td>Use only the physical model, regardless of the state of the cache.</td>
<td>cf memmodel=physical</td>
</tr>
</tbody>
</table>
To configure address translation

You can enable or disable address translation in the emulation probe.

**Address translation configuration**

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
<th>Built-in command</th>
</tr>
</thead>
<tbody>
<tr>
<td>effective</td>
<td>If the MMU is enabled, addresses are verified for proper translation and the corresponding physical address is used instead. (Default)</td>
<td>cf address=effective</td>
</tr>
<tr>
<td>physical</td>
<td>Physical addresses are used, even if the MMU is enabled.</td>
<td>cf address=physical</td>
</tr>
</tbody>
</table>

When the MMU is enabled (MSR[IR] or MSR[DR] is set), and the emulation probe is configured for effective addresses, all memory addresses given to the emulation probe are assumed to be effective addresses (logical addresses). The emulation probe uses the MMU block address translation (BAT) registers, segment registers, hash tables, and other special-purpose MMU registers to compute each corresponding physical address. The requested memory operation is then performed using the physical address.

Operational notes:

- The emulation probe attempts to perform address translation only if the MSR[IR] and/or the MSR[DR] bits are set (=1) AND the emulation probe is configured to do translation (cf address=effective).
- If both the MSR[IR] and MSR[DR] are set, the emulation probe will perform address translations by first searching the IBAT registers and then the DBAT registers. Note that the PowerPC silicon allows the IBAT and DBAT registers to specify overlapping effective address ranges. Avoid defining overlapping ranges. These make debugging more difficult because the emulation probe can use the IBATs to translate addresses intended for the DBATs.
- If an effective address is not found in the MMU translation tables, the emulation probe will return an error and will not perform the requested operation.
- Cache coherency is maintained during emulation probe MMU translations.
- Be sure the translation enable/disable condition is the same when you set and clear breakpoints. If a breakpoint is set while translation is enabled.
and then cleared while translation is disabled, the result will be erroneous and unpredictable. This is also true if a breakpoint is set while translation is disabled and then cleared while translation is enabled.

- The emulation probe ignores read-only restrictions defined in the MMU. (In other words, the emulation probe may attempt to write to memory that has been defined by the MMU as read-only.)
- MMU translation is automatic and transparent to debuggers connected to the emulation probe.

To configure checkstop status

The checkstop signal (CSTP_OUT on pin 15 of the JTAG connector) can be used to detect a checkstop condition.

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
<th>Built-in command</th>
</tr>
</thead>
<tbody>
<tr>
<td>off</td>
<td>The signal is not polled. <em>(Default)</em></td>
<td>cf checkstop=off</td>
</tr>
<tr>
<td>on</td>
<td>The checkstop signal is used to detect a checkstop condition. If a checkstop condition is detected, a prompt of 'c&gt;' is returned on the command line.</td>
<td>cf checkstop=on</td>
</tr>
</tbody>
</table>
To configure the Break In SMB port

If you have an emulation probe, but you do not have an emulation module, use the following table to configure the behavior of the Break In SMB connector on the front of the emulation probe.

When the emulation probe is connected to an emulation module via the module/probe interconnect cable, this configuration item is always set to rising for compatibility with intermodule triggering.

If you need to break on a falling edge, either trigger from the logic analysis system or use the emulation probe without the emulation module.

### Break in configuration

<table>
<thead>
<tr>
<th>Value</th>
<th>Emulation probe Break In</th>
<th>Built-in command</th>
</tr>
</thead>
<tbody>
<tr>
<td>rising</td>
<td>The emulation probe will cause a break into monitor on a rising edge. <em>(Default)</em></td>
<td>cf breakin=rising</td>
</tr>
<tr>
<td>falling</td>
<td>The emulation probe will cause a break into monitor on a falling edge.</td>
<td>cf breakin=falling</td>
</tr>
<tr>
<td>off</td>
<td>Inputs to Break In will be ignored.</td>
<td>cf breakin=off</td>
</tr>
</tbody>
</table>

There is a delay of about 400 μsec between receiving the edge and stopping the processor.
To configure the Trigger Out SMB port

If you have an emulation probe, but you do not have an emulation module, use the following table to configure the behavior of the Trigger Out SMB connector on the front of the emulation probe.

If you have an emulation module, the trigger out behavior is always set to monhigh for compatibility with intermodule triggering.

<table>
<thead>
<tr>
<th>Value</th>
<th>Emulation probe Trigger Out will be</th>
<th>Built-in command</th>
</tr>
</thead>
<tbody>
<tr>
<td>monhigh</td>
<td>Logic high when the processor is running in background. (Default)</td>
<td>cf trigout=monhigh</td>
</tr>
<tr>
<td>monlow</td>
<td>Logic low when the processor is running in background.</td>
<td>cf trigout=monlow</td>
</tr>
<tr>
<td>fixhigh</td>
<td>Fixed logic high.</td>
<td>cf trigout=fixhigh</td>
</tr>
<tr>
<td>fixlow</td>
<td>Fixed logic low.</td>
<td>cf trigout=fixlow</td>
</tr>
</tbody>
</table>
Chapter 7: Configuring the Emulation Probe

Configuring the Emulation Probe for Maximum Performance

To configure restriction to real-time runs

This option enables or disables restriction to real-time runs implemented for all commands other than "rst", "b", "s" and "r".

Real-time runs configuration

<table>
<thead>
<tr>
<th>Value</th>
<th>Emulation module configured for</th>
<th>Built-in command</th>
</tr>
</thead>
<tbody>
<tr>
<td>no</td>
<td>If the processor is running user code, a request for a register or memory display will put the processor in monitor mode, read the requested register(s), then restore the processor to running user code. <em>(Default)</em></td>
<td>cf rrt=no</td>
</tr>
<tr>
<td>yes</td>
<td>If the processor is running user code, a request for a memory or register display will return: !ERROR 647! Restricted to Real Time.</td>
<td>cf rrt=yes</td>
</tr>
</tbody>
</table>

If your debugger allows displaying or modifying memory or registers while the processor is running, you must set rrt=no in order to use that feature.
To set the memory read delay

The memory read delay is provided for accessing slow devices like memory mapped IO.

The memory read delay delays all memory reads the amount of time calculated using parameters entered by the user. The user specifies the core clock frequency. The user adjusts the delay with the number of clock cycles entered.

**Built-in command**

```
ct mrddelcyc= <clock cycles> @ <core clock speed>
```

Example: `ct mrddelcyc=300@400`

This delays all reads 750 ns (300 cycles at 400 MHz).

**Values**

0-4000000000 clock cycles @ 100-700 MHz core clock speed.
*(Default = 0 delay.)*

**Meaning**

Delays all memory reads by the amount of time calculated from user inputs.

The number of clock cycles should be set to the smallest number possible for best performance since it delays all memory reads by the amount of time calculated.
To set the memory write delay

The memory write delay is provided for accessing slow devices like memory mapped IO.

The memory write delay delays all memory writes the amount of time calculated using parameters entered by the user. The user specifies the core clock frequency. The user adjusts the delay with the number of clock cycles entered.

<table>
<thead>
<tr>
<th>Built-in command</th>
</tr>
</thead>
<tbody>
<tr>
<td>cf mwrdelcyc= &lt;clock cycles&gt; @ &lt;core clock speed&gt;</td>
</tr>
</tbody>
</table>

Example: cf mwrdelcyc=300@400
This delays all writes 750 ns (300 cycles, at 400 MHz).

<table>
<thead>
<tr>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-4000000000 clock cycles @ 100-700 MHz core clock speed. (Default = 0 delay.)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Delays all memory writes by the amount of time calculated from user inputs.</td>
</tr>
</tbody>
</table>

The number of clock cycles should be set to the smallest number possible for best performance since it delays all memory writes by the amount of time calculated.
To configure the voltage reference

The emulation probe uses the $V_{\text{ref}}$ signal on the JTAG connector to determine logic high and logic low levels when driving the TDI and TCK signals.

**Voltage Reference Configuration**

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
<th>Built-in command</th>
</tr>
</thead>
<tbody>
<tr>
<td>external</td>
<td>The voltage reference is generated by the target system. (Default)</td>
<td>cf vref=external</td>
</tr>
<tr>
<td>value</td>
<td>The voltage reference of $\text{value}$ is generated internally by the emulation probe. The value is a number followed by either mV, which indicates the value is in millivolts, or V, which indicates the value is in volts.</td>
<td>cf vref=value</td>
</tr>
</tbody>
</table>

**CAUTION:**

This option should only be used if the core voltage is different than that of the $V_{\text{ref}}$ signal on the JTAG connector. Use this option with extreme care, because it is possible to damage the target system if the voltage level is chosen incorrectly.

To configure the voltage threshold

Threshold for voltage reference. Voltages above ($V_{\text{ref}} \times \text{thresh}$) will be considered logic high and voltages below this level will be considered logic low.

**Voltage Threshold configuration**

<table>
<thead>
<tr>
<th>Value</th>
<th>Built-in command</th>
</tr>
</thead>
<tbody>
<tr>
<td>1/2 (Default)</td>
<td>cf thresh=1/2</td>
</tr>
<tr>
<td>2/3</td>
<td>cf thresh=2/3</td>
</tr>
<tr>
<td>1/3</td>
<td>cf thresh=1/3</td>
</tr>
</tbody>
</table>
Memory mapped registers  
(MPC8255 and MPC8260/64/65/66only)

The base address of the processor's memory map is defined by the IMMR register. The target system sets the value of the IMMR at reset. You need to set the corresponding value in the emulation probe so that the emulation probe knows the location of the memory-mapped registers. Use the `cf rstimmr` configuration item to tell the emulation probe the reset value of the IMMR register.

Use a 32-bit hexadecimal value. Only the upper 16 bits are programmed into the IMMR, the lower 16 bits are read-only. The default value is 0f000000.

### Configuration register

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
<th>Built-in command</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>The address value specifies the location of the memory mapped registers.</td>
<td><code>cf rstimmr=address value</code></td>
</tr>
</tbody>
</table>

To configure 32-bit mode  
(MPC8240, MPC8241, and MPC8245 only)

You can enable or disable 32-bit mode.

### 32-bit mode configuration

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
<th>Built-in command</th>
</tr>
</thead>
<tbody>
<tr>
<td>off</td>
<td>Normal, 64-bit mode. <em>(Default)</em></td>
<td><code>cf 32bitmode=off</code></td>
</tr>
<tr>
<td>on</td>
<td>The maximum memory access size is forced to 32 bits. Do not enable this option unless it is specifically supported by your target system.</td>
<td><code>cf 32bitmode=on</code></td>
</tr>
</tbody>
</table>
Chapter 7: Configuring the Emulation Probe

To enable or disable processor caches

MPC82XX processors have instruction and data caches. Debugging using a third party debugger will have the greatest performance if the caches are disabled during debugging.

To turn off the caches clear bits HID0[ICE] and HID0[DCE]. This will turn off the instruction and data caches. You may need to ensure that your start up code does not enable the caches.

You may also debug with the caches enabled. To achieve maximum performance you should disable and invalidate the caches while downloading a program. You can do this by setting bits HID0[ICFI] and HID0[DCFI]. After downloading a program you may want to enable the caches by setting bits HID0[ICE] and HID0[DCE].

Performance will be slower when debugging with the caches enabled due to the emulation probe making sure the cache information stays coherent with the physical memory.
Using the Emulation Probe
Chapter 8: Using the Emulation Probe

Using the Emulation Probe

The emulation probe can be controlled through the following interfaces:

- A third-party debugger. This is the most practical interface to use with the emulation probe. See page 83.
- The emulation control interface of an Agilent Technologies 16700-series logic analysis system. See page 85 or 86.
- The emulation probe’s command line interface. This low-level interface is generally used only for troubleshooting. See page 133.

Before you can use the Emulation Probe you must:

1. Connect the emulation probe to a LAN. See “Connecting the Emulation Probe to a LAN” on page 37.
2. Connect the emulation probe to your target system. See “To connect the emulation probe to the target system” on page 61.
3. Configure the emulation probe for your target system. See “Configuring the Emulation Probe” on page 63.
4. Confirm that the emulation probe is working with your target.

To confirm that the emulation probe can communicate with your target system, try a few simple commands using the emulation probe’s command line interface. Instructions for using the command line interface are on page 133. You can read registers, read memory, or run a simple NOP loop. See page 134 and page 134 for examples.

If the emulation probe can not control the target system, see Chapter 12, “Troubleshooting the Emulation Probe,” beginning on page 123.

When using the emulation probe with a 16700-series logic analysis system, the display can be exported to a web browser, a workstation, or a personal computer (PC).
Several prominent companies design and sell state-of-the-art source debuggers that work with Agilent emulation modules and emulation probes.

Benefits of using a debugger

The debugger will enable you to control the execution of your processor from the familiar environment of your debugger. Using a debugger lets you step through your code at the source-code level.

With a debugger connection, you can set breakpoints, single-step through source code, examine variables, and modify source code variables from the debugger interface. The debugger can also be used to download executable code to your target system.

Using a debugger to connect to the emulation probe allows the entire design team to have a consistent interface from software development to hardware/software integration.

Debugger interfaces must be ordered directly from the debugger vendor.

Compatibility with other logic analysis system tools

You can use your logic analysis system to collect and analyze trace data while you use your debugger. You can use a web browser to display the logic analyzer windows right next to your debugger.

Minimum requirements

To use a debugger with the emulation probe, you will need:

- A debugger which is compatible with the emulation probe
- A LAN connection to the PC or workstation that is running the debugger
  See Chapter 4, “Connecting the Emulation Probe to a LAN,” beginning on page 37.
- A web browser or X windows or an X terminal emulator, such as Reflection X on a PC. This is required only if you wish to have the logic analysis system user interface displayed on your PC or workstation screen, along with the debugger.
Chapter 8: Using the Emulation Probe

Using the Emulation Probe with a Debugger

**Is your debugger compatible with the emulation probe?**

Ask your debugger vendor whether the debugger can be used with an Agilent emulation module or emulation probe.

**Compatibility with the Emulation Control Interface**

*CAUTION:*

Do not use the Emulation Control Interface at the same time as a debugger. The Emulation Control Interface and debuggers do not keep track of commands issued by other tools. If you use both at the same time, the tools may display incorrect information about the state of the processor, possibly resulting in lost data.

**Connecting to an Emulation Module**

If you are using an E5901B emulation module, configure your debugger to use the IP address of the E5900B emulation probe, not the logic analysis system.

You may need to tell the debugger which port number to use. The default port number for a debugger connection is 6470.

Do not use the Emulation Control Interface at the same time as a debugger.
Using the emulation probe with a 16700-series logic analysis system via an emulation module

The following instructions explain how to control the emulation probe through an Agilent 16700-series logic analysis system which has an emulation module installed.

1. Select the emulation module icon in the System window.

2. Select Connect to Emulator... from the menu choices.

3. Select the Connect to Emulator button.

4. The emulation Run Control window will appear, which lets you use the Emulation Control Interface.
Chapter 8: Using the Emulation Probe

Using the emulation probe with a 16700-series logic analysis system via a LAN connection

The following instructions explain how to use the emulation probe via a LAN connection to an Agilent 16700-series logic analysis system.

1 Select the emulation probe icon in the Workspace window.

**NOTE:** Use the scroll bar on the left side of the window to locate this icon.

2 Select **Connect to Emulator...** from the menu choices.

3 Enter the emulation probe’s LAN name or IP address and select the Connect to Emulator button.
4 The emulation Run Control window will appear.
Using the Emulation Probe Command Line Interface

The emulation probe has some built-in commands (also called the “terminal interface”) that you can use for troubleshooting, or to verify that you can communicate with the emulation probe. See “To use the built-in commands” on page 134.

You can enter the built-in commands using:

- A telnet (LAN) connection (see page 88).
- The Command Line window in the Emulation Control Interface of a logic analysis system (see page 89).
- A "command window" in your debugger (see your debugger software instructions).
- A serial connection (see page 42).

Establishing a telnet connection to the emulation probe prior to using the command line interface

You can establish a telnet connection to the emulation probe if:

- A host computer and the probe are both connected to a local-area network (LAN), and
- The host computer has the telnet program (often part of the operating system or an internet software package).

To establish a telnet connection:

1 Find out the LAN address or LAN name of the emulation probe.
2 Start the telnet program.
   If the LAN name of the emulation probe is “test2”, the command might look like this:
   ```
telnet test2
   ```
3 If you do not see a prompt, press the <Return> key a few times.
   To exit from this telnet session, type <CTRL>D at the prompt.
Using the command line interface from the logic analysis system

1 Connect to the emulator. See “Using the Emulation Probe” on page 81 for step-by-step instructions.

2 From the Run Control menu bar select Window, then select the emulator, and select Command Line....

3 The command line window will be displayed. You can enter commands in the “Command Input” field of the Command Line window.
Exporting the Logic Analysis System’s Display

The Agilent 16700-series logic analysis system’s display can be exported to:

- A web browser
- A workstation
- A personal computer

To export the logic analysis system’s display to a web browser

You can export the display of an Agilent 16700-series logic analysis system to your PC or workstation using a web browser. See the online help in your logic analysis system for more information.

To export the logic analysis system’s display to a UNIX workstation

By exporting the logic analyzer's display, you can see and use the logic analysis system's windows on the screen of your workstation. To do this, you must have telnet software and X window installed on your computer.

1. On the workstation, add the host name of the logic analysis system to the list of systems allowed to make connections:

   ```bash
   xhost +<IP_address>
   ```

2. Use telnet to connect to the logic analysis system.

   ```bash
   telnet <IP_address>
   ```

3. Log in as “logic”.

   The logic analysis system will open a Session Manager window on your display.

4. In the Session Manager window, select Start Session on This Display.
Example

On a UNIX workstation, you could use the following commands to export the display of a logic analysis system named “mylogic”:

```
$ xhost +mylogic
$ telnet mylogic
Trying...
Connected to mylogic.mycompany.com.
Escape character is '^]'.
Local flow control on
Telnet TERMINAL-SPEED option ON

Agilent Logic Analysis System
Please Log in as: logic [displayname:0]
login: logic
Connection closed by foreign host.
```

To export the logic analysis system’s display to a PC

By exporting the logic analyzer's display, you can see and use the logic analysis system's windows on the screen of your PC. To do this, you must have telnet software and an X terminal emulator installed on your computer. The following instructions use the Reflection X emulator from WRQ, running on Windows 95, as an example.

1 On the PC, start the X terminal emulator software.
   To start Reflection X, select the Reflection X Client Startup icon.

2 Start a telnet connection to the logic analysis system.
   Log in as “logic”.
   For Reflection X, enter the following values in the Reflection X Client Startup dialog:
   a In the Host field, enter the LAN name or IP address of the logic analysis system.
   b In the User Name field, enter “logic”.
   c Leave the Password field blank.
   d Leave the Command field blank.
   e Select Run to start the connection.

The logic analysis system will open a Session Manager window on your display.
3 In the Session Manager window, select **Start Session on This Display**.
Testing Target System Memory
Two ways to run the memory tests

Many times when a system under test fails to operate as expected, you will need to determine whether the failure is in the hardware or the software. These tests verify operation of the memory hardware in the system under test.

Two ways to run the memory tests

There are two methods for accessing and running the emulation probe's built-in memory tests:

- Through the Emulation Control Interface of a 16700-series logic analysis system
- Using a command line interface (also called terminal interface)

You can use the command line interface through a terminal emulator or through a command window in your debugger.
Two ways to run the memory tests

Using the memory tests with an Agilent 16700 logic analysis system

2. From the menu bar select Window, then select the emulator, and select Memory...

3. Select the Memory Test... button and set up the test in the window that appears.

4. Select the test type and set the parameters in the window that appears.

5. For help using the memory tests select Help from the menu bar, then select On This Window.
Using the memory tests from a command line interface

You can use the memory tests from a command line interface via a telnet session or via the emulator command window of your debugger. You can initiate a telnet connection by issuing a telnet to the emulation probe's IP address from a terminal window.

See Chapter 4, “Connecting the Emulation Probe to a LAN,” beginning on page 37 for instructions on making a connection to the emulation probe which will allow you to access the emulation probe via a command line interface.

For general memory test syntax information, enter the following command at the emulation probe command line interface:

```
help mtest
```

This will display the following help dialog:

```
help mtest
This will display the following help dialog:

mtest - memory test     General Help:

Syntax Parameters:
-a    memory access size (1,2,4,8 bytes)
-v    verbosity level (level of detail of output)
      -v1 prints end summary only
      -v2 prints status at the end of each repetition
      -v3 prints status at the end of each rep. and up to 10 errors
      -v4 prints status at the end of each rep. and all errors.
-r    number of repetitions to be executed
=start> memory test start address
=end> memory test end address
=pattern> pattern to be written to memory

The following applies to the oscilloscope tests:
  Default repetitions is -r0 (repeat forever).
  Default verbosity is -v1.
  Default access size is provided by mo.

The following applies to all other tests:
  Maximum value for repetitions is 10,000.
  Default verbosity is -v3.
  Default access size is provided by mo.

For more details type 'help mtest <test>'
```
Memory Test Patterns

You can use the memory test feature of the emulation probe to perform seven different types of tests. Use these tests to find problems in address lines, data lines, and data storage. Use these tests in combination because no single test can perform a complete evaluation of the target system memory.

The emulation probe provides the following memory tests:

- Basic Pattern - to validate data read-write lines.
- Address Pattern - to validate address read-write lines.
- Rotate Pattern - to validate data read-write lines, and test voltage and ground bounce.
- Walking Ones - to validate individual storage bits in memory.
- Walking Zeros - to validate individual storage bits in memory.
- Oscilloscope Read - to generate the signals associated with reading from memory so they can be viewed on an oscilloscope.
- Oscilloscope Write - to generate the signals associated with writing to memory so they can be viewed on an oscilloscope.
Chapter 9: Testing Target System Memory

Memory Test Patterns

Recommended Test Procedure

Two types of tests are offered for testing target memory: oscilloscope tests, and memory functionality tests.

Oscilloscope Tests

1. Connect the oscilloscope to view activity on the bits of interest.
2. Start an Oscilloscope Read (see page 108) or Oscilloscope Write (see page 109) test, as desired.

The test activity will be written onto the bits you specified continuously until you cancel the test.

Use both the Oscilloscope Read test and the Oscilloscope Write test to thoroughly check the connections of interest.

Memory Functionality Tests

1. Run the Basic Pattern (see page 99) test on the entire Memory Range.

   Result:
   - No Problems. Perform the Address Pattern (see page 102) test next.
   - Problems found. Refer to “If problems were found by the Basic Pattern test” on page 100.

2. Run the Address Pattern (see page 102) test on the entire Memory Range.

   Result:
   - No Problems.
   - Problems found. Refer to “If problems were found by the Address Pattern test” on page 103.

If no problems were found by the Basic Pattern test and the Address Pattern test above, you can ignore the rest of the tests. The memory in your system has been tested thoroughly and it is good.
Basic Pattern test

The Basic Pattern test finds data bits in the specified memory range that are stuck high or low. It also detects data lines that may be tied to power, ground, or not connected at all.

How the Basic Pattern test works

This test writes the Pattern and the complement of the Pattern to the Memory Range, and then compares the values in memory with what was written. The complement of the Pattern and then the Pattern are then written, read, and compared.

Example:

Entering the command

```
mtest bp -a4 -v1 -r2 20000000..2000000f=55555555
```

will produce the following memory writes and reads:

<table>
<thead>
<tr>
<th>First Write/Read</th>
<th>Second Write/Read</th>
</tr>
</thead>
<tbody>
<tr>
<td>20000000</td>
<td>55555555</td>
</tr>
<tr>
<td>20000008</td>
<td>AAAAAAAA</td>
</tr>
<tr>
<td>55555555</td>
<td>AAAAAAAA</td>
</tr>
<tr>
<td>20000008</td>
<td>55555555</td>
</tr>
<tr>
<td>2000000f</td>
<td>55555555</td>
</tr>
</tbody>
</table>

If no errors were found, the following output would appear on your screen:

```
M>mtest bp -a4 -v1 -r2 20000000..2000000f=55555555
Starting: Basic Pattern Test
Completed: Basic Pattern Test
Summary: 2 - PASSED
```

Instructions for using the Basic Pattern test

For help about performing a specific memory test using the Agilent 16700-series logic analysis system, see page 95.

To use the Basic Pattern test from the command line interface, enter

```
mtest bp <parameters>
```

To see a list of the required parameters, enter

```
? mtest bp
```

For general instructions on using the command line interface see page 88.
Chapter 9: Testing Target System Memory
Memory Test Patterns

Interpreting Basic Pattern test results

Consistent errors such as a particular bit incorrect every four bytes typically indicate a problem with the data lines. Random or sparse errors may indicate hardware data memory errors—check individual locations with the Walking Ones and Walking Zeros tests.

This test will halt and generate an error message if your Memory Range specification causes this test to be performed outside the range of valid memory in your target system.

This test will not halt but it will generate an error message if it is run on ROM or on locations with data line or location errors.

You can open a memory window on your logic analyzer to view the memory content. Expect to see the pattern and the complement of the pattern that was specified.

This test will not always detect errors in the address lines. For example, if a bit in the address lines is stuck high or low, the Pattern Test will write to a different location in memory. Then the read from memory for comparison will also be made from that different location so the data will be correct. Use the Address Pattern test with this test to completely evaluate the memory range.

If problems were found by the Basic Pattern test

Below are two examples of problems found by the Basic Pattern test.

<table>
<thead>
<tr>
<th>Example 1: Consistent error</th>
</tr>
</thead>
<tbody>
<tr>
<td>Starting: Basic Pattern Test</td>
</tr>
<tr>
<td>Error: 1 at address 00000200:</td>
</tr>
<tr>
<td>Read</td>
</tr>
<tr>
<td>Expected</td>
</tr>
<tr>
<td>Error: 2 at address 00000204:</td>
</tr>
<tr>
<td>Read</td>
</tr>
<tr>
<td>Expected</td>
</tr>
<tr>
<td>Error: 3 at address 00000208:</td>
</tr>
<tr>
<td>Read</td>
</tr>
<tr>
<td>Expected</td>
</tr>
<tr>
<td>Error: ...</td>
</tr>
<tr>
<td>Read</td>
</tr>
<tr>
<td>Expected</td>
</tr>
</tbody>
</table>

Assume the data line bit associated with the error is stuck high. This could happen if the suspected data line bit were soldered to power.
Chapter 9: Testing Target System Memory

Memory Test Patterns

For an additional test of suspected memory, perform the Walking Ones (see page 106) and Walking Zeros (see page 107) tests on the problem memory range.

Example 2: Random errors

Starting: Basic Pattern Test
Error: 1 at address 00000200:
  Read     8000 (1000 0000 0000 0000)
  Expected 0000 (0000 0000 0000 0000)
Error: 2 at address 000004a2:
  Read     efff (1110 1111 1111 1111)
  Expected ffff (1111 1111 1111 1111)
Repetition: 1 - FAILED found 2 errors
Completed: Basic Pattern Test
Summary: 1 of 1 - FAILED (2 errors total)

From the above listing, we assume there are two location errors in memory. At location 200, there is a bit stuck high. At location 4a0, there is bit stuck low. Use the Walking Ones and Walking Zeros tests to verify the errors.

There is one bit stuck high at location 200 so the Walking Zeros test will print one error message when it tests this location. Use the Walking Ones test to isolate the bit that is stuck low at location 4a0. Again, this will print only one error message.
Address Pattern test

This test verifies that the address lines of the selected memory range are without error.

How the Address Pattern test works

This test writes the address of each memory location as data to each location. The data is then read back to see if it matches the address.

The pattern written to the memory is generated at the start of the test and is dependent upon the start address, access size, and the number of bytes in the memory range.

Depending on the last Access Size selected, subsets of the addresses may be written to memory.

Example:

If the last access size was 1 byte, address 00000001 will have 01 written to it, and address 00000002 will have 02 written to it.

The data written in address 00001000 will look like this, depending on the last Access Size.

<table>
<thead>
<tr>
<th>Access Size</th>
<th>Data Written</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 Byte</td>
<td>00 01 02 03 04 05 06 07 08 09 0a 0b 0c 0d 0e 0f</td>
</tr>
<tr>
<td>2 Byte</td>
<td>1000 1002 1004 1006 1008 100a 100c 100e</td>
</tr>
<tr>
<td>4 Byte</td>
<td>00001000 00001004 00001008 0000100c</td>
</tr>
<tr>
<td>8 Byte</td>
<td>00001000 00001000 00001000 00001000</td>
</tr>
</tbody>
</table>

The upper four bytes of an 8 Byte access size are not tested for a 4 Byte address. The upper four bytes will always be zeros. Use a smaller access size to test these locations with the Address Pattern test.

Unless the access size is 1 Byte, the odd bits of the memory locations will not be tested. Use the Basic Pattern test to check the odd bits.

Instructions for using the Address Pattern test

For help about performing a specific memory test using the Agilent 16700-series logic analysis system, see page 95.

To use the Address Pattern test from the command line interface, enter `mtest ap <parameters>`. To see a list of the required parameters, enter...
Chapter 9: Testing Target System Memory

Memory Test Patterns

? mtest ap.

For general instructions on using the command line interface see page 88.

Interpreting Address Pattern test results

This test does not ensure that the data lines or individual data locations are without error. If a bit is stuck in a memory location, but is stuck in the written value, the stuck bit will not be detected.

You can view the memory in an analyzer memory window of a 16700-series logic analysis system by selecting Window <emulator> Memory... Enter ? m at the command line prompt for help viewing memory using a terminal interface. You should see direct correlation between each address and the data stored at that address.

Consistent errors typically indicate problems in the address lines. This is especially likely if the results of the Basic Pattern test were without errors. Errors in specific memory locations may indicate errors in the memory hardware instead of the address lines.

If problems were found by the Address Pattern test

You may see no errors in the Basic Pattern test, but errors in the Address Pattern test. For example, you might see the following result in the Address Pattern test:

<table>
<thead>
<tr>
<th>Example:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Error: 1 at address 00000000:</td>
</tr>
<tr>
<td>Read</td>
</tr>
<tr>
<td>Expected</td>
</tr>
<tr>
<td>Error: 2 at address 00000002:</td>
</tr>
<tr>
<td>Read</td>
</tr>
<tr>
<td>Expected</td>
</tr>
</tbody>
</table>

You would see that the data stored at locations 00 through 0f is the data that should be at locations 20 through 2f. This indicates an address line problem. Address bit 5 must be stuck low because the addresses that should have been written to the range 20 through 2f were written instead to 00 through 0f.

Random errors typically do not indicate address line errors. Use the Walking Ones (see page 106) and Walking Zeros (see page 107) tests to check the locations of random errors.
Chapter 9: Testing Target System Memory

Memory Test Patterns

Rotate Pattern test

The Rotate Pattern test finds data bits in memory that are stuck high or low. It also detects data lines that may be tied to power ground, or not connected at all. This test can be used to test voltage and ground bounce problems associated with the selected memory range.

How the Rotate Pattern test works

This test writes the Pattern and the complement of the Pattern to the Memory Range, and then compares the values in memory with what was written. Next, the rotated Pattern and the rotated complement of the Pattern are written, read, and compared. Now the Pattern is rotated again, and again it is written, read, and compared. This continues until the rotations of the pattern return it to its original arrangement. That constitutes one Repetition of the Rotate Pattern test.

Example:

<table>
<thead>
<tr>
<th>Address</th>
<th>First Write/Read</th>
<th>Second Write/Read</th>
<th>Third Write/Read</th>
</tr>
</thead>
<tbody>
<tr>
<td>00000000</td>
<td>01</td>
<td>FE</td>
<td>02</td>
</tr>
<tr>
<td>00000001</td>
<td>FE</td>
<td>02</td>
<td>FD</td>
</tr>
<tr>
<td>00000002</td>
<td>02</td>
<td>FD</td>
<td>04</td>
</tr>
<tr>
<td>00000003</td>
<td>FD</td>
<td>04</td>
<td>FB</td>
</tr>
<tr>
<td>00000004</td>
<td>04</td>
<td>FB</td>
<td>08</td>
</tr>
<tr>
<td>00000005</td>
<td>FB</td>
<td>08</td>
<td>F7</td>
</tr>
<tr>
<td>00000006</td>
<td>08</td>
<td>F7</td>
<td>10</td>
</tr>
<tr>
<td>00000007</td>
<td>F7</td>
<td>10</td>
<td>EF</td>
</tr>
<tr>
<td>00000008</td>
<td>10</td>
<td>EF</td>
<td>20</td>
</tr>
</tbody>
</table>

Larger Access Size selections take more time because they require more patterns to be written to all locations (2-byte Access Size requires writing 32 patterns, and 4-byte Access Size requires writing 64 patterns).

The Access Size you select will affect the appearance of memory when you view memory after a test. When a test is complete, memory contains the last set of patterns that was written to it.
Chapter 9: Testing Target System Memory

Memory Test Patterns

Instructions for using the Rotate Pattern test

Since the Rotate Pattern test is designed to rotate a single bit through memory, it is generally best to use a pattern such as 01, 0001, or 00000001.

For help about performing a specific memory test using the Agilent 16700-series logic analysis system, see page 95.

To use the Rotate Pattern test from the command line interface, enter

```
mtest rp <parameters>
```

To see a list of the required parameters, enter

```
? mtest rp
```

For general instructions on using the command line interface see page 88.

Interpreting Rotate Pattern test results

You can open a memory window on your logic analyzer to view the memory content. Expect to see the pattern and the complement of the pattern that was specified.

Consistent errors such as a particular bit incorrect every four bytes typically indicate a problem with the data lines. Random or sparse errors may indicate hardware data memory errors—check individual locations with the Walking Ones and Walking Zeros tests.

This test will halt and generate an error message if your Memory Range specification causes this test to be performed outside the range of valid memory in your target system.

Example:

The following listing is from a Rotate Pattern test which was performed one time with an Access Size of 2 bytes, and an initial pattern of 0001.

What you see below is the 32nd set of patterns written to memory during the test.

```
00000000  7fff  0001  fffe  0002  fffd  0004  fffb  0008
00000010  fff7  0010  ffef  0020  ffdf  0040  fbff  0080
00000020  ff7f  0100  feff  0200  fdff  0400  fbff  0800
00000030  f7ff  1000  efff  2000  dfff  4000  bfff  8000
00000040  7fff  0001  ffef  0002  ffdf  0040  fbff  0080
00000050  fff7  0010  ffef  0020  ffdf  0040  fbff  0080
00000060  ff7f  0100  feff  0200  fdff  0400  fbff  0800
00000070  f7ff  1000  efff  2000  dfff  4000  bfff  8000
```
Chapter 9: Testing Target System Memory

Memory Test Patterns

This test will not halt but it will generate an error message if it is run on ROM or on locations with data line or location errors.

Walking Ones test

How the Walking Ones test works

The Walking Ones test finds data bits stuck in logical "0". This test cycles "1" through each bit position in memory, and checks results. It does this by writing and then reading a pattern sequence of ones and zeros from all memory locations in the range.

Example:

The hexadecimal values 01, 02, 04, ... are written to each location in the Memory Range.

<table>
<thead>
<tr>
<th>Address</th>
<th>1st</th>
<th>2nd</th>
<th>3rd</th>
<th>4th</th>
<th>5th</th>
<th>6th</th>
<th>7th</th>
<th>8th</th>
</tr>
</thead>
<tbody>
<tr>
<td>00000000</td>
<td>01</td>
<td>02</td>
<td>04</td>
<td>08</td>
<td>10</td>
<td>20</td>
<td>40</td>
<td>80</td>
</tr>
<tr>
<td>00000001</td>
<td>02</td>
<td>04</td>
<td>08</td>
<td>10</td>
<td>20</td>
<td>40</td>
<td>80</td>
<td>01</td>
</tr>
<tr>
<td>00000002</td>
<td>04</td>
<td>08</td>
<td>10</td>
<td>20</td>
<td>40</td>
<td>80</td>
<td>01</td>
<td>02</td>
</tr>
<tr>
<td>00000003</td>
<td>08</td>
<td>10</td>
<td>20</td>
<td>40</td>
<td>80</td>
<td>01</td>
<td>02</td>
<td>04</td>
</tr>
<tr>
<td>00000004</td>
<td>10</td>
<td>20</td>
<td>40</td>
<td>80</td>
<td>01</td>
<td>02</td>
<td>04</td>
<td>08</td>
</tr>
</tbody>
</table>

1st, 2nd, 3rd, etc. are the first, second, third, etc. complete passes through the memory.

Larger Access Size selections take more time because they require more patterns to be written to all locations (2-byte Access Size requires writing 16 patterns, and 4-byte Access Size requires writing 32 patterns).

Example:

2-byte Access Size writing 16 patterns:

<table>
<thead>
<tr>
<th>Address</th>
<th>1st</th>
<th>2nd</th>
<th>3rd</th>
<th>4th</th>
<th>5th</th>
<th>6th</th>
<th>7th</th>
<th>8th</th>
<th>9th</th>
<th>10th</th>
<th>11th</th>
<th>12th</th>
<th>13th</th>
<th>14th</th>
<th>15th</th>
<th>16th</th>
</tr>
</thead>
<tbody>
<tr>
<td>00000000</td>
<td>0001</td>
<td>0002</td>
<td>0004</td>
<td>0008</td>
<td>0010</td>
<td>0020</td>
<td>0040</td>
<td>0080</td>
<td>0000</td>
<td>0000</td>
<td>0000</td>
<td>0000</td>
<td>0000</td>
<td>0000</td>
<td>0000</td>
<td></td>
</tr>
<tr>
<td>00000001</td>
<td>0002</td>
<td>0004</td>
<td>0008</td>
<td>0010</td>
<td>0020</td>
<td>0040</td>
<td>0080</td>
<td>0100</td>
<td>0000</td>
<td>0000</td>
<td>0000</td>
<td>0000</td>
<td>0000</td>
<td>0000</td>
<td>0000</td>
<td></td>
</tr>
<tr>
<td>00000002</td>
<td>0004</td>
<td>0008</td>
<td>0010</td>
<td>0020</td>
<td>0040</td>
<td>0080</td>
<td>0100</td>
<td>0200</td>
<td>0000</td>
<td>0000</td>
<td>0000</td>
<td>0000</td>
<td>0000</td>
<td>0000</td>
<td>0000</td>
<td></td>
</tr>
<tr>
<td>00000003</td>
<td>0008</td>
<td>0010</td>
<td>0020</td>
<td>0040</td>
<td>0080</td>
<td>0100</td>
<td>0200</td>
<td>0400</td>
<td>0000</td>
<td>0000</td>
<td>0000</td>
<td>0000</td>
<td>0000</td>
<td>0000</td>
<td>0000</td>
<td></td>
</tr>
<tr>
<td>00000004</td>
<td>0010</td>
<td>0020</td>
<td>0040</td>
<td>0080</td>
<td>0100</td>
<td>0200</td>
<td>0400</td>
<td>0800</td>
<td>0000</td>
<td>0000</td>
<td>0000</td>
<td>0000</td>
<td>0000</td>
<td>0000</td>
<td>0000</td>
<td></td>
</tr>
</tbody>
</table>

Instructions for using the Walking Ones test

For help about performing a specific memory test using the Agilent 16700-
series logic analysis system, see page 95.

To use the Walking Ones test from the command line interface, enter `mtest wl <parameters>`. To see a list of the required parameters, enter `? mtest wl`.

For general instructions on using the command line interface see page 88.

---

**Walking Zeros test**

The Walking Zeros test finds data bits stuck in logical "1".

**How the Walking Zeros test works**

This test cycles "0" through each bit position in memory, and checks results.

### Example:

The hex values FE, FD, FB, ... are written to each location in the *Memory Range*.

<table>
<thead>
<tr>
<th>Address</th>
<th>1st</th>
<th>2nd</th>
<th>3rd</th>
<th>4th</th>
<th>5th</th>
<th>6th</th>
<th>7th</th>
<th>8th</th>
</tr>
</thead>
<tbody>
<tr>
<td>00000000</td>
<td>FE</td>
<td>FD</td>
<td>FB</td>
<td>F7</td>
<td>EF</td>
<td>DF</td>
<td>BF</td>
<td>7F</td>
</tr>
<tr>
<td>00000001</td>
<td>FD</td>
<td>FB</td>
<td>F7</td>
<td>EF</td>
<td>DF</td>
<td>BF</td>
<td>7F</td>
<td>FE</td>
</tr>
<tr>
<td>00000002</td>
<td>FB</td>
<td>F7</td>
<td>EF</td>
<td>DF</td>
<td>BF</td>
<td>7F</td>
<td>FE</td>
<td>FD</td>
</tr>
<tr>
<td>00000003</td>
<td>F7</td>
<td>EF</td>
<td>DF</td>
<td>BF</td>
<td>7F</td>
<td>FE</td>
<td>FD</td>
<td>FB</td>
</tr>
<tr>
<td>00000004</td>
<td>EF</td>
<td>DF</td>
<td>BF</td>
<td>7F</td>
<td>FE</td>
<td>FD</td>
<td>FB</td>
<td>F7</td>
</tr>
</tbody>
</table>

1st, 2nd, 3rd, etc. are the first, second, third complete pass through the memory.

Larger *Access Size* selections take more time because they require more patterns to be written to all locations (2-byte *Access Size* requires writing 16 patterns, and 4-byte *Access Size* requires writing 32 patterns).

### Example:

2-byte *Access Size* writing 16 patterns:

<table>
<thead>
<tr>
<th>Address</th>
<th>1st</th>
<th>2nd</th>
<th>3rd</th>
<th>4th</th>
<th>5th</th>
<th>6th</th>
<th>7th</th>
<th>8th</th>
<th>9th</th>
<th>…</th>
<th>16th</th>
</tr>
</thead>
<tbody>
<tr>
<td>00000000</td>
<td>FFFE</td>
<td>FFFD</td>
<td>FFFB</td>
<td>FFF7</td>
<td>FFFE</td>
<td>FFDF</td>
<td>FFBF</td>
<td>FFBF</td>
<td>FFBF</td>
<td>FEFF</td>
<td>…</td>
</tr>
<tr>
<td>00000001</td>
<td>FFFD</td>
<td>FFFB</td>
<td>FFF7</td>
<td>FFFE</td>
<td>FFDF</td>
<td>FFBF</td>
<td>FFBF</td>
<td>FFBF</td>
<td>FFBF</td>
<td>FEFF</td>
<td>…</td>
</tr>
<tr>
<td>00000002</td>
<td>FFFB</td>
<td>FFF7</td>
<td>FFFE</td>
<td>FFDF</td>
<td>FFBF</td>
<td>FFBF</td>
<td>FFBF</td>
<td>FFBF</td>
<td>FFBF</td>
<td>FEFF</td>
<td>…</td>
</tr>
<tr>
<td>00000003</td>
<td>FFF7</td>
<td>FFFB</td>
<td>FFF7</td>
<td>FFFE</td>
<td>FFDF</td>
<td>FFBF</td>
<td>FFBF</td>
<td>FFBF</td>
<td>FFBF</td>
<td>FEFF</td>
<td>…</td>
</tr>
<tr>
<td>00000004</td>
<td>FFFB</td>
<td>FFF7</td>
<td>FFFB</td>
<td>FFF7</td>
<td>FFFE</td>
<td>FFDF</td>
<td>FFBF</td>
<td>FFBF</td>
<td>FFBF</td>
<td>FEFF</td>
<td>…</td>
</tr>
</tbody>
</table>
Chapter 9: Testing Target System Memory

Memory Test Patterns

Instructions for using the Walking Zeroes test

For help about performing a specific memory test using the Agilent 16700-series logic analysis system, see page 95.

To use the Walking Zeroes test from the command line interface, enter `mtest w0 <parameters>`. To see a list of the required parameters, enter `? mtest w0`.

For general instructions on using the command line interface see page 88.

---

Oscilloscope Read test

How the Oscilloscope Read test works

This test repetitively reads the present content from the Memory Range for the number of Repetitions specified, typically reads continuously until cancelled.

NOTE:
The Oscilloscope Read test does not print or store the data it has read. It is usually used to perform timing analysis on target system memory.

Instructions for using the Oscilloscope Read test

Connect your oscilloscope to view signals on the lines to be tested. These will be the signals generated to perform read transactions from the memory in your target system.

When you have finished using your oscilloscope to view the read-from-memory signals:

- If you are using a 16700 logic analysis system, select the Cancel button in the Busy dialog box.
- If you are using the command line interface, press Ctrl+C.

You will see an error message if your test attempts to read memory addresses outside the range of available memory.

For help about performing a specific memory test using the Agilent 16700-series logic analysis system, see page 95.

To use the Oscilloscope Read test from the command line interface, enter `mtest or <parameters>`. To see a list of the required parameters, enter `? mtest` or `help mtest`. For general instructions on using the command
Oscilloscope Write test

How the Oscilloscope Write test works

This test repetitively writes your selected Pattern to the Memory Range for the number of Repetitions specified, typically continuously until cancelled.

If your pattern is larger than the access size, it will be truncated to fit. If your pattern is smaller than the access size, it will be zero-padded to fit.

This test does not generate error messages for unsuccessful write transactions, such as writes to ROM. This test is usually used to perform timing analysis on target system memory.

If desired, you can open a memory window in the logic analyzer and view the memory where the pattern was written. If the memory is ROM or if it contains errors, it may not contain the pattern that was written.

Instructions for using the Oscilloscope Write test

Connect your oscilloscope to view signals on the lines to be tested. These will be the signals generated to perform write transactions to the memory in your target system.

When you have finished using your oscilloscope to view the write-to-memory signals:

- If you are using a 16700 logic analysis system, select the Cancel button in the Busy dialog box.
- If you are using the command line interface, press Ctrl+C.

You will see an error message if your test attempts to write to memory addresses outside the range of available memory.

For help about performing a specific memory test using the Agilent 16700-series logic analysis system, see page 95.

To use the Oscilloscope Write test from the command line interface, enter mtest ow <parameters>. To see a list of the required parameters, enter ? mtest ow.

For general instructions on using the command line interface see page 88.
Updating Firmware
Chapter 10: Updating Firmware

Firmware gives your emulation probe a “personality” for a particular processor or processor family. The MPC82XX firmware is compatible with all of the processors listed on page 4. You do not have to install new firmware when you decide to control a different processor in the MPC82XX family.

After you have connected the emulation probe to your target system, you may need to update the firmware to give it the right personality for your processor.

Update the firmware if:

• You need to change the personality of the emulation probe for a new processor.
• You have an updated version of the firmware from Agilent Technologies.
Chapter 10: Updating Firmware

Updating Firmware When Operating With a Debugger

To display current firmware version information

- Use `telnet` to access the built-in "terminal interface" and use the `ver` command to view the version information for firmware currently in the emulation probe.

To update firmware from the web

To update the firmware, you must have access to the World Wide Web and a PC or a workstation connected to your emulation probe (through a LAN).

2. Follow the instructions on the web site for installing the firmware.

To update firmware from a floppy disk

- Follow the instructions on the README file on the floppy disk.

The firmware can be installed using either a PC or a workstation which can read PC disks.
Chapter 10: Updating Firmware

Updating Firmware With a Logic Analysis System

Always update firmware by installing a processor support package. This will ensure that the version of the Emulation Control Interface software is compatible with the version of the emulation probe firmware. Logic analysis system operating system CD-ROMS include the processor support packages; versions 1.51 and later will include firmware which is compatible with E5900B emulation probes.

To display current firmware version information

1. Open the Update Firmware window.
   For an emulation module: In the system window, select the emulation module and select Update Firmware.
   For an emulation probe: In the Workspace window, drag the emulation probe icon onto the workspace then select Update Firmware.

2. In the Update Firmware window, select Display Current Version.
   There are usually two firmware version numbers: one for “Generics” and one for the personality of your processor.
To update firmware using the Emulation Control Interface

1. End any run control sessions which may be running.

2. Install the processor support package from the CD-ROM, if necessary.

3. Open the Update Firmware window.

   For an emulation module: In the system window, select the emulation module and select Update Firmware....

   For an emulation probe: In the Workspace window, drag the emulation probe icon onto the workspace then select Update Firmware....

4. In the Update Firmware window, select the firmware to load into the emulation module.

5. Select Update Firmware.

   In about 80 seconds, the firmware will be installed and the screen will update to show the current firmware version.

See also

“Installing Software” beginning on page 53 for instructions on how to install the processor support package from the CD-ROM.
To update firmware for an emulation probe using the Setup Assistant

The Setup Assistant is an online tool for connecting and configuring your logic analysis system for microprocessor and bus analysis. The Setup Assistant is available on Agilent 16700-series logic analysis systems.

This menu-driven tool will guide you through the connection procedures for connecting the logic analyzer to an analysis probe, an emulation probe, or other supported equipment. It will also guide you through connecting an analysis probe to the target system.

1 Install the processor support package from the CD-ROM.

2 Start the Setup Assistant by selecting its icon in the system window.

3 Follow the instructions displayed by the Setup Assistant.

See also

Page 56 for instructions on how to install a the processor support package from the CD-ROM.
Installing an Agilent E5902B Emulation Migration Kit
Chapter 11: Installing an Agilent E5902B Emulation Migration Kit

This chapter shows you how to install an Agilent E5902B emulation migration so that you can use your emulation probe with a new processor family.

The E5902B emulation migration can be used with any E5900B emulation probe. It cannot be used with E5900A emulation probes.

Will I need to change the target board adapter?

A target board adapter is supplied with the emulation migration. Some target board adapters are compatible with more than one type of processor.

Use the table below to determine the part number of the target board adapter that you already have. Then use the table to determine the part number of the target board adapter for the processor type that you are migrating to. If the part numbers are the same, you don’t need to change the target board adapter.

<table>
<thead>
<tr>
<th>Processor Type</th>
<th>Use target board adapter</th>
<th>Emulation Migration P/N</th>
</tr>
</thead>
<tbody>

Steps 4 through 7 of the procedure that follows show how to replace the target board adapter.

If you don’t need to replace the target board adapter, proceed to Chapter 10, “Updating Firmware,” beginning on page 111.
To install the emulation migration

**CAUTION:** Electrostatic discharge can damage electronic components. Use grounded wrist straps and mats.

The tools necessary for this procedure are supplied with the emulation migration kit.

1. Turn off power to the emulation probe.
2. Disconnect all cables from the emulation probe, including the power cord, LAN cable, serial cable, module/probe interconnect cable, and target cable.
3. Remove the cover from the emulation probe:
   a. Remove the 2 nuts and 2 screws from the front of the emulation probe.
Chapter 11: Installing an Agilent E5902B Emulation Migration Kit

b  Remove the front panel.

c  Grasp the top cover with one hand. With the other hand, pull the plate on the bottom of the emulation probe, so that the top cover slides off.
4 Remove the 3 nylon screws from the target board adapter.

5 Carefully lift the target board adapter from the main circuit board.

Do not turn on power to the emulation probe when no target board adapter is installed.

You cannot run performance verification tests or make any measurements without a target board adapter.

6 Install the new target board adapter on the main circuit board.

Align both connectors and press down firmly.

7 Replace the 3 nylon screws.
8 Reinstall the cover on the emulation probe:
   a Slide the top cover into place.
   b Assemble the new front panel.

   c Attach the front panel using the 2 screws and 2 nuts.

9 Connect the LAN cable, module/probe interconnect cable (if you will be using the emulation probe with an emulation module), and the LAN cable to the emulation probe. Do not connect a target cable yet.

10 Turn on power to the emulation probe.

11 Update the emulation probe’s firmware.

   See Chapter 10, “Updating Firmware,” beginning on page 111 for instructions on how to update firmware.

12 Run the performance verification test.

   See page 156 for instructions on testing the emulation probe.

13 Connect the emulation probe to your target system.

   See Chapter 6, “Connecting the Emulation Probe to Your Target System,” beginning on page 59 for instructions on how to make this connection.
Troubleshooting the Emulation Probe
Chapter 12: Troubleshooting the Emulation Probe

If you have problems with the emulation probe, your first task is to determine the source of the problem. Problems may originate in any of the following places:

- The connection between the emulation probe and your debugger
- The emulation module or emulation probe itself
- The connection between the emulation probe and the target system
- The target system

You can use several means to determine the source of the problem:

- The troubleshooting guide beginning on the next page
- The status lights on the emulation probe
- The emulation probe performance verification (PV) tests
- The emulation probe's built-in commands

The information in this chapter is presented in the following sections:

- General Troubleshooting
- Status Lights
- Emulation Probe Built-in Commands
- Problems with the Target System
- Problems with the LAN Interface
- Problems with the Serial Interface
- Problems with the Emulation Module
- Problems with the Emulation Probe
- Using the Emulation Probe Terminal Interface
- Returning Parts for Service
General Troubleshooting

If you have trouble using the emulation probe, the following steps may help you identify the problem. This troubleshooting procedure uses the built-in command line interface. For more information on the command line interface, see page 133.

Step 1: Telnet to the emulation probe

Use telnet to connect to the emulation probe across the LAN. (For instructions on how to do this, see “Verifying LAN Communications” on page 51.)

The emulation probe must be reachable via LAN before you can use it.

If you cannot connect to the emulation probe:

- See “Problems with the LAN Interface” on page 150.
- If you need to change the LAN parameters of the emulation probe, see Chapter 4, “Connecting the Emulation Probe to a LAN,” on page 37.

Step 2: Check the prompt

Once you have connected to the emulation probe, press the Enter key a few times and look at the prompt which is displayed.

If a telnet connection to the emulation probe displays the prompt "->"

The "->" prompt indicates that the firmware loaded into the emulation probe is not compatible with the "target board adapter" which is located inside the emulation probe.
Chapter 12: Troubleshooting the Emulation Probe

General Troubleshooting

Try one of the following until you get a different prompt:

- Cycle power on the emulation probe. (Turn off your target power first.)
- Check that the proper firmware is installed for the target board adapter or the type of emulation probe shown on the front panel of the emulation probe.

The proper firmware is installed at the factory but it could accidentally be changed. A "ver" command will display the firmware which is currently loaded. Refer to “Updating Firmware” on page 111 if the firmware is incorrect.

- Run the performance verification tests. Refer to “To run the emulation probe performance verification tests” on page 156.

Connection to the wrong target or connection to the target with the pins connected backward could potentially damage the emulation probe. Use the performance verification tests to validate that the emulation probe itself is working correctly.

**If a telnet connection to the emulation probe displays the prompt "?>"**

The "?>" prompt indicates that the emulation probe is having trouble talking to the target and it doesn’t know what state the target is in.

- Validate that the emulation probe is connect to a powered up target.

Refer to Chapter 6, “Connecting the Emulation Probe to Your Target System,” beginning on page 59.

- Check the emulation probe configuration settings.

Enter the `cf` command to display the configuration settings. Note that some emulation probes must set the processor type with `cf proc=processor_type`.

- Decrease the JTAG communication speed. Some targets need slower speeds to properly communicate.

Use the `cf speed` command.

- Check that the proper firmware is installed for this processor.

See Chapter 10, “Updating Firmware,” beginning on page 111.
Chapter 12: Troubleshooting the Emulation Probe

General Troubleshooting

Step 3: Try some simple commands to control the target

Examples of some commands are listed on page 134.

If the emulation probe has problems controlling the target

The emulation probe might be having problems controlling the target if you see messages such as:

"Cannot break"
"Processor is checkstopped"
"Bad status code (0xff) received from the processor"
Or the prompt changes to "?>"

Problems controlling the target can be caused by a variety of conditions. Typically the problem is in the configuration of the emulation probe or the configuration of the target.

Try the following to better control your target:

• Check that the JTAG signals are being driven properly.

In particular, if your processor requires the QACK signal to be low, and the signal is not low, the emulation probe will not be able to control the processor. See page 26.

• Decrease the JTAG communication speed. Some targets need slower speeds to properly communicate.

If you are using a telnet connection or a debugger command file, use the cf speed command.

• Check the emulation probe configuration settings.

If you are using a telnet connection, enter the cf command to display all of the configuration settings.

Pay particular attention to the cf proc=processor_type line of the output. If you need to change the processor type, you must load the appropriate firmware into the emulation probe (See “Updating Firmware” on page 111.).
Chapter 12: Troubleshooting the Emulation Probe

General Troubleshooting

• Check that the emulation probe is not restricted to real-time runs.

    If you are using a telnet connection or a debugger command file, use the
    `cf rrt=no` command.

    Restrict to real time will not allow you to access memory or registers while the
    target is running. By setting this option to no, you will be able to access the
    memory and registers while the target is running.

• Check that the target processor is configured.

    Some target require configuration registers on the processor to be initialized
    before the emulation probe can properly communicate with the target.

    For example, the MPC860 requires memory chip selects to be defined before
    the target memory can be accessed. Other processors need their memory
    controllers initialized.

    To initialize the target processor, either run your target from reset (if you have
    a BOOT ROM) or define a series of emulation probe commands to initialize the
    target.

    Also refer to “Using the Emulation Probe Command Line Interface” on
    page 133 for additional information about testing a target.

---

Step 4: Check the emulation module

If you are using an E5901B emulation module, select the emulation module
icon and start the Emulation Control Interface.

If you have problems using the emulation probe as an emulation module in a 16700-series logic
analysis system

To use the emulation probe as an emulation module in a 16700-series logic
analysis system you must have installed an E5901B emulation module and you
must connect the emulation probe to the emulation module using the module/probe
interconnect cable. In addition, the emulation probe must be connected
to the logic analysis system using a LAN.

• Check that the emulation probe and the logic analysis system are on
  the LAN.
Chapter 12: Troubleshooting the Emulation Probe

General Troubleshooting

If you are using a site LAN you should be able to ping both the logic analysis system and the emulation probe.

If you are using a point-to-point LAN connection you must use a special crossover LAN cable, such as the one supplied with the emulation module.

The telnet window of the logic analysis system should be able to communicate with the emulation probe. This window can be found by selecting the "System Admin" icon in the main system window.

- Check that the emulation probe is connected to the emulation module with the module/probe interconnect cable.
  If this cable is connected, you should be able to display the firmware version from the "Update Firmware" window.

- Check that you have the proper processor support package installed.
  You can check this by selecting the System Admin icon in the main system window, then looking at the list of software packages installed.

- Test the emulation module. See page 155.
- Test the emulation probe. See page 156.
- Try using the Setup Assistant to configure your measurement setup.

Step 5: Check your debugger connection

If you are using a debugger, try connecting to the emulation probe.

If you have problems using the emulation probe with a debugger

Most problems are associated with not having the emulation probe and target properly configured or initialized.

Some debuggers have an initialization file that needs to be properly defined before a debugger can connect to the emulation probe.

- Make sure the PC or workstation where the debugger is running can ping the emulation probe. (See “To verify LAN communications using ping” on page 51.)
Chapter 12: Troubleshooting the Emulation Probe

General Troubleshooting

- Initialize the emulation probe and target so that the debugger can connect. Refer to your debugger manual for proper initialization.
- Refer to your debugger manual for proper operation.

If you need to obtain help

If, after following the troubleshooting steps and looking through the other sections in this chapter, the emulation probe still is not working:

1. Write down the target processor version, the emulation probe firmware version, and the type of emulation probe (E5900A or E5900B). See page 138 for instructions on how to display the emulation probe firmware version.

2. Call your nearest Agilent Technologies sales or service office.

   To locate a sales or service office near you, go to http://www.tm.agilent.com and select Contact Us.
Chapter 12: Troubleshooting the Emulation Probe

Status Lights

**Emulation Probe Target Status Lights**

The emulation probe uses status lights to communicate various modes and error conditions.

The following table gives more information about the meaning of the power and target status lights.

- ○ = LED is off
- ● = LED is on

### Power/Target Status Lights

<table>
<thead>
<tr>
<th>Pwr/Target LEDs</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>○ RST</td>
<td>No target system power, or emulation probe is not connected to the target system</td>
</tr>
<tr>
<td>○ DBG</td>
<td></td>
</tr>
<tr>
<td>○ RUN</td>
<td></td>
</tr>
<tr>
<td>● RST</td>
<td>Target system is in a reset state</td>
</tr>
<tr>
<td>○ DBG</td>
<td></td>
</tr>
<tr>
<td>○ RUN</td>
<td></td>
</tr>
<tr>
<td>○ DBG</td>
<td>The target processor is in Debug Mode</td>
</tr>
<tr>
<td>● RUN</td>
<td></td>
</tr>
<tr>
<td>○ RST</td>
<td>The target processor is executing user code</td>
</tr>
<tr>
<td>○ DBG</td>
<td></td>
</tr>
<tr>
<td>● RUN</td>
<td></td>
</tr>
<tr>
<td>○ DBG</td>
<td>Only boot firmware is good (other firmware has been corrupted)</td>
</tr>
<tr>
<td>● RUN</td>
<td></td>
</tr>
<tr>
<td>● RST</td>
<td>The emulation probe can no longer control the target. Reset the target, then initialize the emulation probe.</td>
</tr>
<tr>
<td>● DBG</td>
<td></td>
</tr>
<tr>
<td>● RUN</td>
<td></td>
</tr>
</tbody>
</table>
Chapter 12: Troubleshooting the Emulation Probe

Status Lights

**Emulation Probe LAN Status Lights**

The yellow LED, on the right side of the connector, indicates LAN activity (receive or transmit).

The green LED, on the left side of the connector, is lit when the LAN interface is operating in 100Base-Tx mode.

**Emulation Probe Power On Light**

The green LED, to the left of the power switch, is lit when the emulation probe is connected to a power source and the power switch is on.
Using the Emulation Probe Command Line Interface

The emulation probe has some built-in commands (also called the “terminal interface”) which you can use for troubleshooting. See page 88 for instructions on using the command line interface.

To list the emulation probe commands

To list the emulation probe command line mode commands enter:

? *

To get help on an individual command enter

? <command name>

Examples

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>? cf</td>
<td>Help on configuration questions</td>
</tr>
<tr>
<td>? cf speed</td>
<td>Help on configuration speed question</td>
</tr>
</tbody>
</table>
Chapter 12: Troubleshooting the Emulation Probe

Using the Emulation Probe Command Line Interface

To use the built-in commands

Here are a few commonly used built-in commands:

### Overview of Useful built-in commands

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>b</strong></td>
<td>Break—go into the background monitor state</td>
</tr>
<tr>
<td><strong>cf</strong></td>
<td>Configuration—read or write configuration options</td>
</tr>
<tr>
<td><strong>help</strong></td>
<td>Help—display online help for built-in commands</td>
</tr>
<tr>
<td><strong>init</strong></td>
<td>Initialize—<code>init -c</code> re-initializes everything in the emulation probe except for the LAN software and configuration settings</td>
</tr>
<tr>
<td><strong>lan</strong></td>
<td>configure LAN address</td>
</tr>
<tr>
<td><strong>m</strong></td>
<td>Memory—read or write memory</td>
</tr>
<tr>
<td><strong>reg</strong></td>
<td>Register—read or write a register</td>
</tr>
<tr>
<td><strong>mtest</strong></td>
<td>Memory test—test target memory system</td>
</tr>
<tr>
<td><strong>r</strong></td>
<td>Run—start running user code</td>
</tr>
<tr>
<td><strong>rep</strong></td>
<td>Repeat—repeat a command or group of commands</td>
</tr>
<tr>
<td><strong>rst</strong></td>
<td>Reset—reset the target processor</td>
</tr>
<tr>
<td><strong>s</strong></td>
<td>Step—do a low-level single step</td>
</tr>
<tr>
<td><strong>ver</strong></td>
<td>Version—display the product number and firmware version of the emulation probe</td>
</tr>
</tbody>
</table>

Use `help command_name` to see the command syntax. For example, enter `help m` to get help on the memory command.

### Examples of built-in commands

#### Reset, break and run commands

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>rst</strong></td>
<td>To reset the target</td>
</tr>
<tr>
<td><strong>b</strong></td>
<td>To break(stop) the target into debug mode (Background)</td>
</tr>
<tr>
<td><strong>r</strong></td>
<td>To run the target</td>
</tr>
<tr>
<td><strong>r 100</strong></td>
<td>To run the target from an address</td>
</tr>
<tr>
<td><strong>r rst</strong></td>
<td>To run the target from reset</td>
</tr>
</tbody>
</table>
Register commands

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>reg</code></td>
<td>Read all of the registers</td>
</tr>
<tr>
<td><code>reg pc</code></td>
<td>Read the program counter</td>
</tr>
<tr>
<td><code>reg pc r0 r1</code></td>
<td>Read multiple registers</td>
</tr>
<tr>
<td><code>reg pc=200</code></td>
<td>To Set the pc to 0x200</td>
</tr>
</tbody>
</table>

All register and memory values are entered as hexadecimal values and should not be entered with the leading "0x". Use values like "200", NOT "0x200".

Memory commands

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>m 0..ff</code></td>
<td>Display memory from 0 through ff</td>
</tr>
<tr>
<td><code>m -d1 0..ff=0,1,2,3</code></td>
<td>Write 0,1,2,3 repetitively through the memory 0 to ff</td>
</tr>
</tbody>
</table>

Memory test commands

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>mtest bp -a1 0..ff=55</code></td>
<td>Basic pattern test byte access</td>
</tr>
<tr>
<td><code>mtest bp -a4 0..ff=55555555</code></td>
<td>Basic pattern test 4-byte access</td>
</tr>
<tr>
<td>? mtest</td>
<td>Additional test information</td>
</tr>
</tbody>
</table>

To write a NOP loop into memory

**NOTE:**
This example is specific to the PowerPC processor family. Please adapt this example for the processor type you are using.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>b</code></td>
<td>To stop target if not already stopped</td>
</tr>
<tr>
<td><code>reg msr=40</code></td>
<td>Set machine state</td>
</tr>
<tr>
<td><code>reg hid0=c00</code></td>
<td>Disable caches</td>
</tr>
<tr>
<td><code>m -d4 2000=60000000,4bfffffc</code></td>
<td>To write NOP loop into memory</td>
</tr>
<tr>
<td><code>reg pc=2000</code></td>
<td>To Set the pc</td>
</tr>
</tbody>
</table>
Chapter 12: Troubleshooting the Emulation Probe

Using the Emulation Probe Command Line Interface

**To step the program**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>s</td>
<td>Step one instruction</td>
</tr>
<tr>
<td>PC = 00002004</td>
<td>Shows the new location of the PC</td>
</tr>
<tr>
<td>s 10</td>
<td>Step ten instructions</td>
</tr>
<tr>
<td>? s</td>
<td>Additional information on stepping</td>
</tr>
<tr>
<td>? ss</td>
<td>Additional information on source stepping</td>
</tr>
</tbody>
</table>

**To run the simple NOP program**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>r 2000</td>
<td>Run from address 2000</td>
</tr>
<tr>
<td>b</td>
<td>To stop the program</td>
</tr>
<tr>
<td>reg pc</td>
<td>To see the location of the PC register</td>
</tr>
<tr>
<td>r</td>
<td>To continue running the program</td>
</tr>
</tbody>
</table>

**To set a software breakpoint (Memory trap replacement breakpoints)**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bc -e swbp</td>
<td>Enable Software Breakpoints</td>
</tr>
<tr>
<td>bp -p 2004</td>
<td>To set a Software Breakpoint at address 2004</td>
</tr>
<tr>
<td>bp</td>
<td>To review the breakpoints that are set</td>
</tr>
</tbody>
</table>
| r        | To run the program and hit the software breakpoint!
| bp -r *  | To remove all software breakpoints |
To set a hardware breakpoint (On processor breakpoint registers)

(Use this type of breakpoint when debugging ROM)

<table>
<thead>
<tr>
<th>Command</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>bc -d swbp</td>
<td>Disable software breakpoints</td>
</tr>
<tr>
<td>bc -e hwbp</td>
<td>Enable hardware breakpoints</td>
</tr>
<tr>
<td>bc -h -p 2004</td>
<td>To set a hardware breakpoint at address 2004</td>
</tr>
<tr>
<td>r</td>
<td>To run the program and hit the hardware breakpoint !ASYNC_STAT 601! Hardware breakpoint: 00002004</td>
</tr>
<tr>
<td>bp -h -r *</td>
<td>To remove all hardware breakpoints</td>
</tr>
<tr>
<td>? bp</td>
<td>To see additional bp capabilities</td>
</tr>
<tr>
<td></td>
<td>(Hardware Breakpoints can be set on memory transactions also)</td>
</tr>
</tbody>
</table>

To use command line editing

<table>
<thead>
<tr>
<th>Command</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;cntrl&gt;-r</td>
<td>To recall last command(s) backward</td>
</tr>
<tr>
<td>&lt;cntrl&gt;-b</td>
<td>To recall last command(s) forward</td>
</tr>
<tr>
<td>? cl</td>
<td>To show you how to do it</td>
</tr>
<tr>
<td>cl -e</td>
<td>To enable command line editing</td>
</tr>
<tr>
<td>&lt;ESC&gt;</td>
<td>To enter command line editing mode</td>
</tr>
</tbody>
</table>

To build scripts

To build scripts, get the script utility from our web site
Download the script utility. This is a unsupported utility but it will work for most scripts that you may want to build. It is unsupported in that if you find a defect with it we may choose not to fix the defect. The source code of the utility is also available. The emulload utility also has the ability to download ELF, COFF, IEEE695 and S-record files.

To flash memory

This is best left to a debugger interface.
You may also want to use the Emulation Control Interface in the logic analysis system to flash target ROM.
In addition we provide some information at our Web site on how to build scripts to flash parts. Go to http://www.cos.agilent.com/probe and choose Flashing Target ROM.
Chapter 12: Troubleshooting the Emulation Probe
Using the Emulation Probe Command Line Interface

To display the emulation probe firmware version

```
ver
```

See Also

Use the `help` command for more information on these and other commands. Note that some of commands listed in the help screens are generic commands for Agilent emulation probes and may not be available for your product.

If you are writing your own debugger, contact Agilent Technologies for more information.

---

**Emulation probe command line prompts**

The prompt indicates the status of the emulation probe:

**Emulation probe prompts**

<table>
<thead>
<tr>
<th>Prompt</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>U&gt;</td>
<td>Running user program</td>
</tr>
<tr>
<td>M&gt;</td>
<td>Running in background monitor</td>
</tr>
<tr>

<td>No target power</td>
</tr>
<tr>
<td>R&gt;</td>
<td>Emulation reset</td>
</tr>
<tr>
<td>r&gt;</td>
<td>Target reset</td>
</tr>
<tr>
<td>c&gt;</td>
<td>Checkstop</td>
</tr>
<tr>
<td>?&gt;</td>
<td>Unknown state</td>
</tr>
<tr>
<td>-&gt;</td>
<td>Firmware is not properly communicating with the target</td>
</tr>
<tr>
<td></td>
<td>(Try running <code>init -p</code> immediately to correct this condition)</td>
</tr>
<tr>
<td>$</td>
<td>$ with any prompt indicates to a telnet user that the emulator is in use by a debugger or a logic analysis system's Emulation Control Interface</td>
</tr>
</tbody>
</table>

Use `help command_name` to see the command syntax. For example, enter `? m` or `help m` to get help on the memory command.
Chapter 12: Troubleshooting the Emulation Probe
Using the Emulation Probe Command Line Interface

Configuration commands

The following commands are useful to determine whether your emulation probe is working properly.

- `cf proc` Read the current processor choice
- `? cf proc` Show all choices for processor choice
- `cf proc=mpc8240` Set the processor to type Motorola MPC8240
- `cf proc=mpc8260` Set the processor to type Motorola MPC8260
- `cf speed` Read the speed setting
- `cf speed=4M` Set the JTAG communication speed to 4 MHz
- `cf speed=16M` Set the JTAG communication speed to 16 MHz
- `? mtest` Show available memory tests
- `mtest wr -al 0..100` Do a walking ones memory test from memory location 0 to 100
Problems with the Target System

What to check first

Verify that the cf options are correct for your target.

1 Try some basic built-in commands using the Command Line window or a telnet connection:

   U>rst
   U>
   This should reset the target and display a "U>" prompt if 'cf reset=run'.

   U>rst
   M>
   This should reset the target and display an "M>" prompt if 'cf reset=stop'.

   M>vads
   If you are using the Motorola MPC8260 VADS evaluation target, this command will configure the memory system.

   M>m 0..=abcd1234
   M>m 0..
   00000000 abcd1234 abcd1234 abcd1234 abcd1234
   00000010 abcd1234 abcd1234 abcd1234 abcd1234
   00000020 abcd1234 abcd1234 abcd1234 abcd1234
   00000030 abcd1234 abcd1234 abcd1234 abcd1234
   00000040 abcd1234 abcd1234 abcd1234 abcd1234
   00000050 abcd1234 abcd1234 abcd1234 abcd1234
   00000060 abcd1234 abcd1234 abcd1234 abcd1234
   00000070 abcd1234 abcd1234 abcd1234 abcd1234
   M>
   This should display memory values starting at address 0.

   M>s
   This should execute one instruction at the current program counter.

If any of these commands don't work, there may be a problem with the design of your target system, a problem with the revision of the processor you are using, or a problem with the configuration of the emulation module.
2. Check that the emulation module firmware matches your processor. To do this, enter:

```
M> ver
```

---

**To check the debug port connector signals**

- Check for the following logic levels on the target debug port.

Levels with the emulation module not connected:

<table>
<thead>
<tr>
<th>Header Pin</th>
<th>Signal Name</th>
<th>Level</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>TDI</td>
<td>Low</td>
</tr>
<tr>
<td>4</td>
<td>TRST</td>
<td>High/Low (depends on pullup or pulldown.)</td>
</tr>
<tr>
<td>6</td>
<td>+POWER</td>
<td>VDD</td>
</tr>
<tr>
<td>7</td>
<td>TCK</td>
<td>High</td>
</tr>
<tr>
<td>9</td>
<td>TMS</td>
<td>High</td>
</tr>
<tr>
<td>11</td>
<td>SRESET</td>
<td>High</td>
</tr>
<tr>
<td>13</td>
<td>HRESET</td>
<td>High</td>
</tr>
<tr>
<td>15</td>
<td>CHECKSTOP</td>
<td>High</td>
</tr>
<tr>
<td>16</td>
<td>GND</td>
<td>Low</td>
</tr>
</tbody>
</table>

Levels with the emulation module connected:

<table>
<thead>

</tbody>
</table>
To interpret the initial prompt

The initial prompt can be used to diagnose several common problems. To get the most information from the prompt, follow this procedure:

1. Connect the emulation module to your target system.

2. Set the default configuration settings. Enter:

   M>cf default

   If you are using the MPC8240, also enter:

   M>cf proc=MPC8240

   You can enter this command at any prompt. The emulation module will respond with the same information as printed by the “ver” command.

   - If the response is “!ERROR 905! Driver firmware is incompatible with ID of attached device”
     Make sure the target interface module is connected to the cable of the emulation module, then try the “init -c” command again.

   - If the initial prompt is “p>”
     Check pin 6 on header, 3.3V (VDD).

   - If the initial prompt is “M>”
     The processor entered debug mode without the help of the emulation module. Is another debugger connected?

   - If the initial prompt is “c>”
     Processor is checkstopped. Something caused a machine exception before the emulation module connected or CHECKSTOP is being pulled or held low.

   - If the initial prompt is “?>”
     A bad status code (0xXX) was received from the processor. Valid status is 0x01 or 0x05. Any other status indicates a bad scan of the instruction register. Check TCK, TDO, TDI, TMS, and TRST signals. Check the firmware revision.

   - If the initial prompt is “U>”
     Processor is running and the emulation module is scanning the instruction register correctly.
Chapter 12: Troubleshooting the Emulation Probe

Problems with the Target System

Now you can do some more tests:

3 Enter the reset command:

```
U>rst
U>
```

If the prompt after \texttt{rst} is "?>"  
A bad status code (0xXX) was received from the processor. Valid status is 0x01, any other status indicates bad scan of the instruction register or failure of the reset signals. Verify TCK, TDO, TDI, TMS, and TRST are all changing state on an \texttt{HRESET}.

If the \texttt{rst} command fails  
Set "cf reset=stop" (no external bus cycles used in this mode), then enter the "rst" command again:

```
*>cf reset=stop
*>rst
M>
```

You can enter these commands at any prompt, shown here as "*>".

- If the prompt is "M>" with no error messages, all scans worked. We have control as long as we don’t try to run code.

- If an error message is displayed, verify that \texttt{HRESET} and \texttt{SRESET} are being driven.

- If the prompt is "c>", there was bad scanning of the data scan chain. Check processor mask revision.

- If the prompt is "U>", the processor failed to stop soft or hard. Check reset lines, mask revision, processor type and firmware version.

If the prompt after \texttt{rst} is "Us>"  
The \texttt{HRESET} and \texttt{SRESET} lines are working.
Chapter 12: Troubleshooting the Emulation Probe

Problems with the Target System

Continue with more tests:

4 Enter the break command:

U>b
M>

If the prompt after b is "M>" with error messages
If you see: "!ERROR 145! Unable to soft stop - freezing the processor clocks" the processor is hard stopped. Check the mask revision, processor type, and firmware version. If all of these look good, the target may not be terminating cycles (pending external bus cycles). Successive run ("r") and step ("s") commands will fail. The processor may have fetched an invalid instruction.

Check the value of the PC (IAR):

M>reg PC
   reg PC= xxxxxxxx
M>

If the value is fff00100, the processor had a problem accessing the boot ROM and crashed during boot.

Processor and/or board level reset is required to recover from "freezing processor clocks" -- register and memory commands should still work.

If the prompt after b is "M>" with no error messages
Everything is still working correctly.

If you can get to the "M>" prompt, continue with more tests:

5 At the "M>" prompt, check register and memory access:

M>reg r0=12345678
M>reg r0
   reg r0=12345678
M>

If the returned value is equal to the written value, then the VDD level of the
chip is probably correct.

Now enter:

M>m -d4 -a4 0=11111111,22222222,33333333,44444444
M>m -d4 -a4 0..

If the target memory system is configured, this should write abcd1234 to memory starting at 0 and then read back the same values.

M>

• Returned value is equal to the written value implies that memory is working.

• Returned value is not equal to the written value implies that memory control may not be initialized. Try to initialize by:

M>cf reset=run;rst;w 5
  #waiting for 5 seconds...
U>b
M>

• Repeat above memory test.

• Check memory access size using the mo command:

M>mo

• Check access size matches target memory -a0. The default access size -a0 is the 64-bit access.

M>mo -d4 -a0

• Repeat above memory test.
6 At the "M>" prompt, check the processor's revision level:

For example:

M> reg pvr
  reg pvr=xxxxxxxx
M>

At the time of this release both 8240 and 8260 will return a value of 00910101 or 00810101.

If you see memory-related problems

1 Enter:

```
M>m -d4 -a4 0=11111111,22222222,33333333,44444444
M>m -d4 -a4 0...
  00000000 11111111 02222222 33333333 44444444
  00000010 00000000 00000000 00000000 00000000
  00000020 00000000 00000000 00000000 00000000
  00000030 00000000 00000000 00000000 00000000
  00000040 00000000 00000000 00000000 00000000
  00000050 00000000 00000000 00000000 00000000
  00000060 00000000 00000000 00000000 00000000
  00000070 00000000 00000000 00000000 00000000
M>
```

- RAM must be at address 0.
- Read value not equal to the written value implies that the memory controller is not setup correctly.
2 Hand load a small program:

```
start 1000=38210001   addi r1,r1,1   #Increment r1 by 1
  1004=60000000   nop
  1008=60000000   nop
  100c=4bfffff4   b   start      #Loop back to start
```

The opcode 0x4bfffff4 is a branch to a relative offset, so this program can be placed at any start address.

```
M>reg r1=0
M>m -a4 -d4 1000=38210001,60000000,60000000,4bfffff4
```

Verify that stepping the program will increment the register.

```
M>s
M>reg r1
M>reg r1=00000001
```

Run the program and check the value of reg r1.

```
M>r 1000
U>reg r1
  reg r1=00034567 # or some number
U>reg r1
  reg r1=00102333 # or some number
U>
```

This program will loop forever, incrementing r1. This is a good test program to load once a memory system is up to make sure the microprocessor can run code from memory.

If the processor spontaneously runs after break

Running from reset may cause problems. To ensure proper operation clear the software watchdog enable bit in the SYPCR register.

If you reset to monitor (set cf reset=stop, see page 69) the problem won’t happen because the emulation probe writes to the SYPCR and clears the software watchdog enable bit.
Chapter 12: Troubleshooting the Emulation Probe
Problems with the Target System

If you see the "!ASYNC_STAT 173!" error message

If after a break, the following error arises:

!ASYNC_STAT 173! MSR.RI bit not set - Break may not be recoverable

This indicates that the MSR.RI bit is not set, implying that a non-maskable break was needed, and the interrupt may not be recoverable. If this occurs while breaking out of regular code, then the MSR.RI bit was not set in the boot code. This can be fixed by 'ORing' in 0x00000002 into the SRR1 register and resuming the run.

If you see the “!ERROR 145!” error message

If the following error arises:

!ERROR 145! Unable to soft stop - freezing the processor clocks

The processor is in an unstable state and should be reset via a hard reset or a power-on reset. The 'rst' command may not be able to bring the processor into a known state.
Other error messages

The following is a list of unique error messages that may be encountered for this product.

- **!ERROR 644! Could not update IMMR register**
  Check the value of the cf_rstimmr configuration item. See page 79.

- **!ERROR 644! cf_immr does not match actual IMMR**
  Code executed on the target system may have changed the value of the IMMR.

- **!ERROR 644! Unable to modify SYPCR register**
  Check the value of the cf_rstimmr configuration item. See page 79.

- **!ERROR 644! Register <reg> does not match its shadow segment register**
  To synchronize the segment register with its shadow register, write a value to the segment register. For example: m>reg sr0=0.
Problems with the LAN Interface

If you cannot verify LAN communication

If you cannot verify connection using the procedure in "To verify LAN communication", or if commands are not accepted by the emulation probe:

- Make sure that you have connected the emulation probe to the proper power source and that the power light is lit.
- Make sure that you wait for the power-on self test to complete before connecting.
- Check that the Emulation Control Interface or debugger was configured with the correct LAN address. If the emulation probe is on a different subnet than the host computer, check that the gateway address is correct.
- Make sure that the emulation probe’s IP address is set up correctly. To do this, connect the emulation probe to a terminal or terminal emulator and enter the `lan` command. (See “To configure LAN parameters using a serial connection” on page 42.)
- Make sure that the gateway address is set up correctly. The default gateway address of 0.0.0.0 does not allow the emulation probe to communicate with computers on other subnets.
- If you have just changed the IP address of the emulation probe, leave the emulation probe powered on and connected to the LAN for a few minutes, then try again. Some hubs, routers, and hosts maintain tables of IP addresses and link-level addresses. It may take a while for these tables to be updated.
- Make sure that the proper LAN cable is connected.
  - Use a Category 5 cable if your connection is running at 100 Mbps (100BASE-TX).
  - For a point-to-point connection, use a crossover cable.
  - For a LAN connection, use a regular LAN cable, not a crossover cable (the cable supplied with the emulation module, part number 5061-7342, is a crossover cable).
Chapter 12: Troubleshooting the Emulation Probe

Problems with the LAN Interface

- Watch the LAN LEDs to see whether the emulation probe is seeing LAN activity. The LEDs are described on page 132. Refer to your LAN documentation for information on testing connectivity.

- It’s also possible for there to be a problem with the emulation probe firmware while the LAN interface is still up and running. In this case, you must reboot the emulation probe by turning the emulation probe power switch off then on again.

If you have LAN connection problems

- Verify the IP address and gateway mask of the emulation probe. To do this, connect the emulation probe to a terminal or terminal emulator and enter the `lan` command. (See “To configure LAN parameters using a serial connection” on page 42.)

If it takes a long time to connect to the network

- Check the subnet masks on the other LAN devices connected to your network. All of the devices should be configured to use the same subnet mask.

  Subnet mask error messages do not indicate a major problem. You can continue using the emulation probe.

  If there are many subnet masks in use on the local subnet, the logic analysis system may take a very long time to connect to the network after it is turned on.

If you have problems setting the LAN parameters using a logic analysis system

- If the E5900B emulation probe is not connected to an E5901B emulation module, then make sure the emulation probe is on the same subnet as the logic analysis system during initial setup; otherwise, probe LAN address
problems with the LAN interface

setup will fail. After initial setup, you can modify the emulation probe's LAN parameters using the Emulation Control Interface before moving the probe to a different subnet.

Another thing that will cause emulation probe LAN address setup to fail is a BOOTP daemon, running elsewhere on your network, that is configured to respond to the link-level address of the emulation probe.
Problems with the Serial Interface

If you cannot verify RS-232 communication

If the emulation probe prompt does not appear in the terminal emulator window:

- Make sure that you have connected the emulation probe to the proper power source and that the power switch is on.
- Make sure that you have properly configured the data communications parameters on the host computer.
- Verify that you are using the correct cable. Use the cable and adapter which are supplied with the emulation probe.

If you have RS-232 connection problems with the MS Windows Terminal program

- Use the "HyperTerminal" program (usually found in the Accessories windows program group) and set up the "Communications..." settings as follows:
  - Baud Rate: 9600
  - Data Bits: 8
  - Parity: None
  - Stop Bits: 1
  - Flow Control: None
  When you are connected, hit the Enter key. You should get a prompt back.
- If you still don't get a prompt, make sure the serial cable is connected to the correct port on your PC.
- Make sure you are using the serial cable which was supplied with the emulation probe.

With certain RS-232 cards, connecting to an RS-232 port where the emulation
Problems with the Serial Interface

probe is turned off (or is not connected) will hang the PC. The only way to get control back is to reboot the PC. Therefore, we recommend that you always turn on the emulation probe before attempting to connect via RS-232.
Problems with the Emulation Module

Occasionally you may suspect a hardware problem with the emulation module. The procedure in this section describes how to test the emulation module hardware, and if a problem is found, how to repair or replace the broken component.

This procedure tests the hardware within the logic analysis system—the emulation module and its connection to the logic analysis system. To test the emulation probe, see page 156.

To test the emulation module

1. End any Emulation Control Interface or debugger sessions.
2. Disconnect the emulation probe from the target system.
3. In the system window, select the System Admin icon.
4. Select the Admin tab.
5. Select Self-Test....
6. Read the Question dialog and select Yes if you wish to run the self tests.
7. Select the Master Frame tab.
8. Select the E5901B Emulation Module.
9. Select Test All.
10. When you are finished running self tests, select Quit. Then restart your session from the Session Manager window.
Problems with the Emulation Probe

To run the emulation probe performance verification tests

In addition to the powerup tests, there are several additional performance verification (PV) tests available.

These tests can be performed through a 16700-series logic analysis system or via a serial or telnet connection.

Before running probe performance verification:

- Leave the emulation probe connected to the LAN and to the power supply or module/probe interconnect cable.
- Leave the target board adapter installed inside the emulation probe.
- End any Emulation Control Interface or debugger sessions.
- Disconnect the target cable from the target system. (Power off the emulation probe while you do this.)
- Connect an SMB cable (such as Agilent 16532-61601) from the "Break In" connector to the "Trigger Out" connector on the front panel of the emulation probe. (If you aren’t concerned about these signals, you may omit this step and ignore any related test failures.)

To run the performance verification tests using the logic analysis system

1. End any Emulation Control Interface or debugger sessions.
2. Turn off the emulation probe and disconnect the emulation probe from your target system, then turn the emulation probe on again.
Chapter 12: Troubleshooting the Emulation Probe

Problems with the Emulation Probe

3 In the system window, select the emulation probe icon then select Performance Verification.

4 Select Start PV.

The results will appear on screen.

To run complete performance verification tests using a serial or telnet connection

1 Connect an SMB cable (such as Agilent 16532-61601) between BREAK IN and TRIGGER OUT on the front panel of the emulation probe.

2 Disconnect the probe/module interconnect cable.

3 Turn off the emulation probe and disconnect the emulation probe from your target system, then turn the emulation probe on again.

4 Connect the emulation probe to your PC or workstation using a serial or LAN connection, as described in “Connecting the Emulation Probe to a LAN” on page 37.

5 Use a telnet or a terminal emulator to connect to the emulation probe.

6 Enter the pv 1 command.

See Also Options available for the pv command are explained in the help screen
Chapter 12: Troubleshooting the Emulation Probe

Problems with the Emulation Probe

displayed by typing `help pv` or `? pv` at the prompt.

<table>
<thead>
<tr>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>Here are some examples of ways to use the pv command.</td>
</tr>
</tbody>
</table>

To execute all of the tests one time:

```
pv 1
```

The results on a good system, with the trigger out and break in SMBs connected, should similar to the following.

```
U>pv 1
Testing: HPE8130A Series Emulation System
Test  1: Powerup PV Results                          Passed!
Test  2: Emulation Module Port Feedback Test         Passed!
Test  3: Run Control FPGA Test                        Passed!
Test  4: Run Control Clock Test                       Passed!
Test  5: Break In and Trigger Out SMB Feedback Test  Passed!
Test  6: Target Board Adapter Feedback Test (FACTORY ONLY) Not Executed
FAILED Number of tests: 1 Number of failures: 0
```

The product numbers and version information will be different for your emulation probe. The product numbers displayed are for the various pieces of firmware and will be different from the product number you used to order the product.

To execute test 2 with maximum debug output repeatedly until a Ctrl-c is entered:

```
pv -t2 -v9 0
```

If a performance verification test fails

There are some things you can do if a failure is found on one of the tests. Details of the failure can be obtained through using a `-v` value (“verbose level”) of 9.
If there are random problems

Occasionally development systems for the PowerPC using the Agilent emulation probe can experience erratic behavior, or random target connection and operation errors or failures. Two major causes for these problems are:

- Crosstalk between the JTAG signals on the cable between the emulation probe and the target.
- Noise from the external fields being coupled into the target connection cable. Major external fields that can affect this connection include the startup and shutdown of nearby fluorescent lamps and CRTs. Universal motors in appliances such as vacuum cleaners and floor buffers can generate significant field impulses.

The following is two potential solutions to the problems mentioned above.

1. Reduce the TCK clock rate. A reduction from 32 MHz to 10 MHz (cf speed = 10 M) can cause up to a 50% reduction in the crosstalk. The most significant side effect is a reduction in download rate. If the increase in download times cannot be tolerated the TCK clock rate can be increased for the duration of the download time, then reduced to gain the increased reliability while debugging.

2. Provide an additional ground path between the emulation probe and the target system. The SMB connections on the front of the emulation probe provide a solid ground connection.

If the particular failure you see is not listed below, contact Agilent Technologies for assistance.

Test 1: Powerup PV Results
Failure of this test indicates a hardware problem with the emulation probe. Contact Agilent Technologies for assistance.

Test 2: Emulation Module Port Feedback Test
Failure of this test indicates a hardware problem with the emulation probe. Contact Agilent Technologies for assistance.

This test exercises the hardware which drives the connection to the emulation
Chapter 12: Troubleshooting the Emulation Probe

Problems with the Emulation Probe

module. It does not test the module/probe interconnect cable.

The test is not executed if the emulation probe is connected to an emulation module.

Test 3: Run Control FPGA Test
Test 4: Run Control Clock Test

Failure of these tests indicates a hardware problem with the emulation probe. Contact Agilent Technologies for assistance.

If the emulation probe fails one of these tests, it may have been damaged by electrostatic discharge through the target cable. To prevent such damage in the future, follow standard ESD preventive practices.

Test 5: Break In and Trigger Out SMB Feedback Test

Before returning to Agilent Technologies, check to ensure that you have connected a good cable between the two SMB connectors.

Test 6: Target Board Adapter Feedback Test

Failure of this test indicates a hardware problem with the emulation probe. Contact Agilent Technologies for assistance.

This test exercises the I/O circuitry. If the test passes, but the emulation probe seems to have trouble communicating with the target system, the problem is probably with the target system.

If this test was not executed, it means that the target board adapter you are using does not support the test.
Returning Parts for Service

The repair strategy for this emulation probe is board replacement.

Exchange assemblies are available when a repairable assembly is returned to Agilent Technologies. These assemblies have been set up on the “Exchange Assembly” program. This lets you exchange a faulty assembly with one that has been repaired, calibrated, and performance verified by the factory. The cost is significantly less than that of a new assembly.

To return a part to Agilent Technologies

1. Follow the procedures in this chapter to make sure that the problem is caused by a hardware failure, not by configuration or cabling problems.

2. In the U.S., call 1-800-403-0801. Outside the U.S., call your nearest Agilent sales office. Ask them for the address of the nearest service center.

   To locate a sales or service office near you, go to [http://www.tm.agilent.com](http://www.tm.agilent.com) and select Contact Us.

3. Package the part and send it to the Agilent service center.

   Keep any parts which you know are working. For example, if only a cable is broken, keep the emulation probe.

4. Agilent will repair or replace the part and send it back to you.

   The unit returned to you will have the same serial number as the unit you sent to Agilent.

   In some parts of the world, on-site repair service is available. Ask an Agilent sales or service representative for details.
To obtain replacement parts

The following table lists some parts that may be replaced if they are damaged or lost. Not all parts are shipped with every product. The part numbers are subject to change. Contact your nearest Agilent Technologies sales office for further information.

### Exchange assemblies

To clean the instrument

If the instrument requires cleaning:

1. Remove power from the instrument.

2. Clean the instrument using a soft cloth that has been moistened in a mixture of mild detergent and water.

3. Make sure that the instrument is completely dry before reconnecting it to a power source.
Chapter 12: Troubleshooting the Emulation Probe

Returning Parts for Service
Specifications and Characteristics
Chapter 13: Specifications and Characteristics

The following operating characteristics are not specifications, but are typical operating characteristics for the Agilent Technologies E5900B emulation probe and E5901B emulation module.

---

Operating characteristics

The following operating characteristics are not specifications, but are typical operating characteristics.
Input/Output Electrical Characteristics

Trigger Out SMB Port

With a 50 Ω load, a logic high is ≥ 2.0 V, and a low is ≤ 0.4 V. The output function is selectable (see “To configure the Trigger Out SMB port” on page 74).

Break In SMB Port

Edge-triggered TTL level input, 20 pF, with 4.6 kΩ to ground in parallel. Maximum input: +5 V to -5 V when the emulation probe is powered OFF; +10 V to -5 V when the emulation probe is powered ON. Input function is selectable (see “To configure the Break In SMB port” on page 73).

Communication Ports

Serial Port

RJ12 connector (DB9-to-RJ12 adapter and serial cable included). RS-232 DCE to 9600 baud, 8-bit, no parity, one stop bit.

IEEE 802.3 Type 10/100Base-TX LAN Port

RJ-45 connector, is compatible with both 10 Mbps (10Base-T) and 100 Mbps (100Base-TX) twisted-pair ethernet LANs.

Power Supply

Input. 100-240 V, 1.0 A, 50/60 Hz, IEC 320 connector.

Output. 12 V, 3.3 A

CAT I (Mains isolated).

Emulation module environmental characteristics

The Agilent E5901B emulation module meets the environmental characteristics of the logic analysis system in which it is installed.

For indoor use only.
Glossary

**Analysis Probe**  A probing solution connected to the target microprocessor. It provides an interface between the signals of the target microprocessor and the inputs of the logic analyzer. Formerly called a “preprocessor.”

**Background Debug Monitor**  Also called Debug Mode, In Background, or In Monitor. The normal processor execution is suspended and the processor waits for commands from the debug port. The debug port commands include the ability to read and write memory, read and write registers, set breakpoints and start the processor running (exit the Background Debug Monitor).

**Debug Mode**  See Background Debug Monitor.

**Debug Port**  A hardware interface designed into a microprocessor that allows developers to control microprocessor execution, set breakpoints, and access microprocessor registers or target system memory using a tool like the emulation probe.

**Elastomeric Probe Adapter**  A connector that is fastened on top of a target microprocessor using a retainer and knurled nut. The conductive elastomer on the bottom of the probe adapter makes contact with pins of the target microprocessor and delivers their signals to connection points on top of the probe adapter.

**Emulation Migration Kit**  The hardware and software required to use an emulation probe with a new processor family.

**Emulation Module**  An emulation module is installed within the mainframe of a logic analysis system. An E5901A emulation module is used with a target interface module (TIM) or an analysis probe. An E5901B emulation module is used with an E5900B emulation probe and does not use a TIM.

**Emulation Probe**  An emulation probe is a standalone instrument connected via LAN to the mainframe of a logic analyzer or to a host computer. It provides run control within an emulation and analysis test setup. Formerly called a "processor probe" or "software probe."

**Emulator**  An emulation module or an emulation probe.

**Extender**  A part whose only function is to provide connections from one location to another. One or more extenders might be stacked to
Glossary

raise a probe above a target microprocessor to avoid mechanical contact with other components installed close to the target microprocessor. Sometimes called a "connector board."

**Flexible Adapter** Two connection devices coupled with a flexible cable. Used for connecting probing hardware on the target microprocessor to the analysis probe.

**Gateway Address** An IP address entered in integer dot notation. The default gateway address is 0.0.0.0, which allows all connections on the local network or subnet. If connections are to be made across networks or subnets, this address must be set to the address of the gateway machine.

**General-Purpose Flexible Adapter** A cable assembly that connects the signals from an elastomeric probe adapter to an analysis probe. Normally, a male-to-male header or transition board makes the connections from the general-purpose flexible adapter to the analysis probe.

**High-Density Adapter Cable** A cable assembly that delivers signals from an analysis probe hardware interface to the logic analyzer pod cables. A high-density adapter cable has a single MICTOR connector that is installed into the analysis probe, and two cables that are connected to corresponding odd and even logic analyzer pod cables.

**High-Density Termination Adapter Cable** Same as a High-Density Adapter Cable, except it has a termination in the MICTOR connector.

**In Background, In Monitor** See Background Debug Monitor.

**Inverse Assembler** Software that displays captured bus activity as assembly language mnemonics. In addition, inverse assemblers may show execution history or decode control busses.

**IP address** Also called Internet Protocol address or Internet address. A 32-bit network address. It is usually represented as decimal numbers separated by periods; for example, 192.35.12.6.

**Jumper** Moveable direct electrical connection between two points.

**JTAG (OnCE) port** See debug port.

**Label** Labels are used to group and
identify logic analyzer channels. A label consists of a name and an associated bit or group of bits.

**Link-Level Address** The unique address of the LAN interface. This value is set at the factory and cannot be changed. The link-level address of a particular piece of equipment is often printed on a label above the LAN connector. An example of a link-level address in hexadecimal: 080090012AB. Also known as an LLA, Ethernet address, hardware address, physical address, or MAC address.

**Mainframe Logic Analyzer** A logic analyzer that resides on one or more board assemblies installed in a 16500, 1660-series, or 16600/700-series mainframe.

**Male-to-male Header** A board assembly that makes point-to-point connections between the female pins of a flexible adapter or transition board and the female pins of an analysis probe.

**MICTOR Connector** A high-density matched impedance connector manufactured by AMP Corporation. *High-density adapter cables* can be used to connect the logic analyzer to MICTOR connectors on the target system.

**Monitor, In** See *Background Debug Monitor*.

**Pod** A collection of logic analyzer channels associated with a single cable and connector.

**Preprocessor** See *Analysis Probe*.

**Preprocessor Interface** See *Analysis Probe*.

**Probe Adapter** See *Elastomeric Probe Adapter*.

**Processor Probe** See *Emulation Probe*.

**Run Control Probe** See *Emulation Probe* and *Emulation Module*.

**Setup Assistant** Wizard software program which guides a user through the process of connecting and configuring a logic analyzer to make measurements on a specific microprocessor. The setup assistant icon is located in the main system window.

**Shunt Connector**. See *Jumper*.

**Solution** Historical term for a set of tools for debugging your target system. A solution included probing, inverse assembly, the B4620B Source
Correlation Tool Set, and an emulation module.

**Stand-Alone Logic Analyzer** A standalone logic analyzer has a predefined set of hardware components which provide a specific set of capabilities. A standalone logic analyzer differs from a mainframe logic analyzer in that it does not offer card slots for installation of additional capabilities, and its specifications are not modified based upon selection from a set of optional hardware boards that may be installed within its frame.

**State Analysis** A mode of logic analysis in which the logic analyzer is configured to capture data synchronously with a clock signal in the target system.

**Subnet Mask** A subnet mask blocks out part of an IP address so the networking software can determine whether the destination host is on a local or remote network. It is usually represented as decimal numbers separated by periods; for example, 255.255.255.0.

**Symbol** Symbols represent patterns and ranges of values found on labeled sets of bits. Two kinds of symbols are available:
1) Object file symbols — Symbols from your source code, and symbols generated by your compiler. Object file symbols may represent global variables, functions, labels, and source line numbers.
2) User-defined symbols — Symbols you create.

**Target Board Adapter** A daughter board inside the E5900B emulation probe which customizes the emulation probe for a particular microprocessor family. The target board adapter provides an interface to the ribbon cable which connects to the debug port on the target system.

**Target Control Port** An 8-bit, TTL port on a logic analysis system that you can use to send signals to your target system. It does not function like a pattern generator or emulation module, but more like a remote control for the target’s switches.

**Target Interface Module** A small circuit board which connects the 50-pin cable from an E5901A emulation module or E5900A emulation probe to signals from the debug port on a target system. Not used with the E5900B emulation probe.

**TIM** See Target Interface Module.

**Timing Analysis** A mode of logic analysis in which the logic analyzer is
configured to capture data at a rate determined by an internal sample rate clock, asynchronous to signals in the target system.

**Transition Board** A board assembly that obtains signals connected to one side and rearranges them in a different order for delivery at the other side of the board.

**Trigger Specification** A set of conditions that must be true before the instrument triggers. See the printed or online documentation of your logic analyzer for details.

**1/4-Flexible Adapter** An adapter that obtains one-quarter of the signals from an elastomeric probe adapter (one side of a target microprocessor) and makes them available for probing.

Regulatory Information for Canada
ICES/NMB-001
This ISM device complies with Canadian ICES-001.
Cet appareil ISM est conforme à la norme NMB-001 du Canada.

Regulatory Information for Australia/New Zealand
This ISM device complies with Australian/New Zealand AS/NZS 2064.1

Note:
Use standard ESD preventive practices while handling and connecting the E5900B to its target to avoid component damage.
Safety Notices

This apparatus has been designed and tested in accordance with IEC Publication 1010, Safety Requirements for Measuring Apparatus, and has been supplied in a safe condition. This is a Safety Class I instrument (provided with terminal for protective earthing). Before applying power, verify that the correct safety precautions are taken (see the following warnings). In addition, note the external markings on the instrument that are described under "Safety Symbols."

Warnings

- Before turning on the instrument, you must connect the protective earth terminal of the instrument to the protective conductor of the (mains) power cord. The mains plug shall only be inserted in a socket outlet provided with a protective earth contact. You must not negate the protective action by using an extension cord (power cable) without a protective conductor (grounding). Grounding one conductor of a two-conductor outlet is not sufficient protection.
- Only fuses with the required rated current, voltage, and specified type (normal blow, time delay, etc.) should be used. Do not use repaired fuses or short-circuited fuseholders. To do so could cause a shock or fire hazard.
- If you energize this instrument by an auto transformer (for voltage reduction or mains isolation), the common terminal must be connected to the earth terminal of the power source.
- Whenever it is likely that the ground protection is impaired, you must make the instrument inoperative and secure it against any unintended operation.
- Service instructions are for trained service personnel. To avoid dangerous electric shock, do not perform any service unless qualified to do so. Do not attempt internal service or adjustment unless another person, capable of rendering first aid and resuscitation, is present.
- Do not install substitute parts or perform any unauthorized modification to the instrument.
- Capacitors inside the instrument may retain a charge even if the instrument is disconnected from its source of supply.
- Do not operate the instrument in the presence of flammable gases or fumes. Operation of any electrical instrument in such an environment constitutes a definite safety hazard.
- Do not use the instrument in a manner not specified by the manufacturer.

To clean the instrument

If the instrument requires cleaning: (1) Remove power from the instrument. (2) Clean the external surfaces of the instrument with a soft cloth dampened with a mixture of mild detergent and water. (3) Make sure that the instrument is completely dry before reconnecting it to a power source.

Safety Symbols

⚠️ Instruction manual symbol: the product is marked with this symbol when it is necessary for you to refer to the instruction manual in order to protect against damage to the product.

⚡ Hazardous voltage symbol.

Earth terminal symbol: Used to indicate a circuit common connected to grounded chassis.
